## To

My Parents

## Certificate

This is to certify that the thesis entitled 'Studies on some topics in product graphs' submitted to the Cochin University of Science and Technology by Ms. Chithra M.R. for the award of the degree of Doctor of Philosophy under the Faculty of Science is a bonafide record of studies carried out by her under my supervision in the Department of Mathematics, Cochin University of Science and Technology. This report has not been submitted previously for considering the award of any degree, fellowship or similar titles elsewhere.

Dr. A. Vijayakumar (Supervisor)

Professor
Department of Mathematics Cochin University of Science and Technology Cochin- 682022, Kerala.

Cochin-22
02/09/2013.

## Declaration

I, Chithra M.R., hereby declare that this thesis entitled 'Studies on some topics in product graphs' contains no material which had been accepted for any other Degree, Diploma or similar titles in any University or institution and that to the best of my knowledge and belief, it contains no material previously published by any person except where due references are made in the text of the thesis.

Chithra M.R.
Research Scholar (Reg. No.3414)
Department of Mathematics Cochin University of Science and Technology Cochin-682022, Kerala.

# Acknowledgement 

'Gurur Brahma Gurur Vishnu Gurur Devo Maheswara Gurur Saakshat Parahbrahma Thasmai Sree Gurave Namah' with this prayer in my mind, let me express my gratitude to the God Almighty for enabling me to complete my thesis.

I owe a debt of gratitude to my teachers, parents and friends for their support and prayer to complete my research work.

First and foremost I would like to thank my supervisor Dr.A.Vijayakumar, Professor, Department of Mathematics, Cochin University of Science and Technology for the patient guidance, encouragement and advice he has provided throughout my time as his student. His positive outlook and confidence in my research inspired me and gave me confidence. I consider myself very fortunate for being able to work with a very considerate and encouraging professor like him. No words of acknowledgment would be adequate to fully express my gratitude and I shall remain indebted to him for ever.

I am greatful to Prof.P.G.Romeo, Prof.A.Krishnamoorthy, Prof.M.N.N.Nampoothiri, Prof.B.Lakshmy, Prof.R.S.Chakravarti, Prof.M.Jathavedan, and Prof.M.K.Ganapathi for their help and encouragement to complete this study successfully. I would like to thank the current and former office staff and librarian of the Department of Mathematics for their support and help of various kinds. My gratitude also goes to the authorities of Cochin University of Science and Technology for awarding a Junior Re-
search Fellowship during the initial stage of my work. I also thank the PURSE programme of Department of Science and Technology, Government of India for awarding a research fellowship.

I wish to express my sincere thanks to Dr. Manju K. Menon, St.Paul's College, Kalamassery, India for introducing me the notion of the diameter variability and related topics and also for permitting to include our joint work in this thesis.

I wish to express my gratitude to Dr. Daniela Ferrero, Texas State University, USA, who had visited CUSAT during November 2009, under the 'ERUDITE' programme of the Government of Kerala, for the discussion and valuable suggestions given by her at the beginning of my research work. I am also very greatful to Prof. Sandi Klavžar, University of Ljubljana, Slovenia for his insightful ideas and suggestions during my research work.

I am lucky enough to have the support and encouragement of my good fellow researchers. I thank all my Graph Theory friends Dr.B.Radhakrishnan, Dr.K.S. Parvathy, Dr.G.Indulal, Ms.Savitha K.S, Dr.Aparna, Dr.Seema Varghese, Mr.Pravas K., Ms.Anu Varghese, Mr.Tijo and Ms.Seethu for their fruitful discussions and constant encouragement. I wish to express my thanks to my fellow researchers Dr.Varghese Jacob, Dr.Pramod, Dr.Kirankumar, Dr.Sreenivasan, Ms.Deepthi C., Mr.Jayaprasad, Mr.Tonny, Mr.Didimos, Mr.Balesh, Mr.Manikandan, Ms.Raji, Ms.Pami, Ms.Anusha, Ms.Dhanya, and Ms.Akhila for their inspiration.

I would like to thank my Parents - in - law, Mr.Babu and Mrs.Vasanthakumari and brother - in - law Mr.Nakul for encouraging me to finish this piece of work.

I wish to thank my parents, Mr.Mohandas and Ms.Retnabai. Their love and inspiration is my driving force. It is their encouragement and support from the very beginning of my life that made it possible for me to reach this stage. Many thanks to my brother Mr.Amal for his support and being a true brother when needed.

Finally, I would like to acknowledge the most important persons in my life - my husband Mr.Naveen and my daughter Navmi. They have made many sacrifices so that I could pursue my dream. Naveen has been a constant source of strength and inspiration. His love and confidence in me and Navmi's smile made this thesis a reality.

Chithra M.R.

## Chapter 1

## Introduction

The origin of graph theory can be traced back to Euler's work on the Königsberg bridges problem. The Swiss mathematician Leonhard Euler presented a paper 'On the solution of a problem relating to the geometry of position' to his colleagues at the Academy of Sciences in St Petersburg on 26 August 1735. This was the Konigsberg bridges problem - find a closed walk that crosses each of the seven bridges of Königsberg exactly once, which led to the discovery of Eulerian graphs [6]. Since then the subject has grown into one of the most inter disciplinary branches in mathematics with a great variety of applications
[5], [56].

The development of graph theory with its applications to electrical networks, flows and connectivity are included in [10] and [26]. Interest in graphs and their applications has grown exponentially in the past two decades, due to the usefulness of graphs as models for computation and optimization [35].

The idea of networks has received much attraction in the past years as it affects many aspects of our lives, such as how we store and retrieve information, communication etc. The Web graph [5], [24] is a real world network which became an active field of study in the last decade. A web graph, $W$ has vertices representing the web pages and the edges correspond to links between the pages. This exciting notion of web graph has applications in different areas. The most famous ranking algorithm, 'Page Rank' was introduced in 1998, for Google's web search algorithm [11].
'Scale free network' is a network characterized by a 'power law degree distribution'. The construction of scale free graph is based on its adjacency matrix. Many critical infrastructure systems such as internet, railroads, gas pipeline systems etc have
been shown to be scale free [64]. Spectral properties of complex networks are also studied [54]. A large number of biological networks such as metabolic reaction networks, gene regulatory network, food networks between species in an ecosystem have been studied in [27].

In any branch of mathematics we try to get new structures from the given structures. In graph theory also many interesting classes of graphs are obtained by combining graphs in several ways such as join, union, product etc.
'Graph products' are viewed as a convenient method to describe the structure of a graph in terms of its factors. There are three products - Cartesian, strong and lexicographic product which have many applications and theoretical interpretations. These products have the property that projection into at least one factor is a weak homomorphism. For this reason the three standard products are most extensively studied and have the widest range of applications. When dealing with product graphs, one of the main source of reference is the book by $R$. Hammack et al. [36].

An interconnection network may be modeled by a simple
graph whose vertices represent components of the network and the edges represent physical communication links. A basic feature of a network is that its components are connected by physical communication links to transmit information according to some pattern. Many graph theoretic techniques can be used to study the efficiency and reliability of a network, as discussed in [41], [50] and [66]. For designing large-scale interconnection networks, the product graph operation is an important method to obtain large graphs from smaller ones, with a number of parameters that can be calculated from the corresponding parameters of the factor graph.

The distance and diameter of a graph play significant roles in analyzing the efficiency of an interconnection network. The diameter is often taken as a measure of efficiency, when studying the potential effects of link failures on the performance of a communication network, especially for networks with maximum time-delay or signal degradation. In fact, most of the graph products are interconnection networks and a good network must be hard to disrupt and the transmissions must remain connected even if some vertices or edges fail. In order to improve or increase the efficiency of message transmission we need to minimize the
diameter of a graph. However, there are nice interconnection networks, such as butterfly networks, honeycomb networks [41], which are not product graphs.

In the design of an interconnection network, another fundamental consideration is the reliability of the network, which is characterized by the vertex connectivity and the edge connectivity of the network. If some processors or links are faulty, the information cannot be transmitted by these links and the efficiency of network will be affected. These problems deal with how the remaining processors can still communicate with a reasonable efficiency. In terms of graphs, this problem is modeled in the literature as the vulnerability of the diameter. These notions have received much research attention in the past years due to its applications in networks [66].

For routing problems in interconnection networks it is important to find the shortest containers between any two vertices, since the $w$-wide diameter gives the maximum communication delay when there are up to $w-1$ faulty nodes in a network modeled by a graph. The concept of 'wide diameter' was introduced by Hsu [41] to unify the concepts of diameter and connectivity.

The concept of 'domination' has attracted interest due to its wide applications in many real world situations [38]. A connected dominating set serves as a virtual backbone of a network and it is a set of vertices that helps in routing [17].

In this thesis, we make an earnest attempt to study some of these notions in graph products. This include, the diameter variability, the diameter vulnerability, the component factors and the domination criticality.

### 1.1 Basic definitions

The basic notations, terminology and definitions are from [4], [13], [37], [38], [43], [65] and the basic results are from [42], [43], and [36].

Definition 1.1.1. A graph $G=(V, E)$ consists of a nonempty collection of points, $V$ called its vertices and a set of unordered pairs of distinct vertices, $E$ called its edges. The unordered pair of vertices $\{u, v\} \in E$ are called the end vertices of the edge $e=\{u, v\}$. In that case, the vertex $u$ is said to be adjacent to the vertex $v$. Two edges $e$ and $e^{\prime}$ are said to be incident if they have a common end vertex. The neighborhood of a vertex $u$ is the set $N(u)$ consisting of all vertices $v$ which are adjacent to $u$. The closed neighborhood of a vertex $u$ is $N[u]=N(u) \cup\{u\} .|V|$ is called the order of $G$, denoted by $n$ or $n(G)$ and $|E|$ is called the size of $G$, denoted by $m$ or $m(G)$. A graph $G$ is totally disconnected if it has no edges.

Definition 1.1.2. The number of vertices adjacent to a vertex $v$ is called the degree of the vertex, denoted by $\operatorname{deg}(v)$.

A vertex of degree zero is an isolated vertex and of degree one is called a pendant vertex. A vertex of degree $(n-1)$ is called a universal vertex. The maximum and the minimum degree of vertices are denoted by $\Delta(G)$ and $\delta(G)$ respectiively. $G$ is regular if $\Delta(G)=\delta(G)$. It is k-regular, if $\operatorname{deg}(v)=k$ for every vertex $v \in V(G)$.

Definition 1.1.3. A graph $G$ is isomorphic to a graph $H$ if there exists a bijection $\phi: V(G) \rightarrow V(H)$ such that $u$ and $v$ are adjacent in $G$ if and only if $\phi(u)$ and $\phi(v)$ are adjacent in $H$. If $G$ is isomorphic to $H$, we write $G \cong H$.

Definition 1.1.4. A graph $H$ is called a subgraph of $G$ if $V(H) \subseteq V(G)$ and $E(H) \subseteq E(G)$. A subgraph $H$ is a spanning subgraph of $G$ if $V(H)=V(G)$. A subgraph $H$ is called an induced subgraph of $G$ if each edge of $G$ having its ends in $V(H)$ is also an edge of $H$. The subgraph of $G$ induced by $H$ is denoted by $\langle H\rangle$.

Definition 1.1.5. A $v_{0}-v_{k}$ walk in a graph $G$ is a finite list $v_{0}, e_{1}, v_{1}, e_{2}, v_{2}, \ldots, e_{k}, v_{k}$ of vertices and edges such that for $1 \leqslant i \leqslant k$, the edge $e_{i}$ has end vertices $v_{i-1}$ and $v_{i}$. If the vertices $v_{0}, v_{1}, \ldots, v_{k}$ of the above walk are distinct, then it is
called a path. A path from the vertex $u$ to the vertex $v$ is called a $\mathbf{u}-\mathbf{v}$ path. A path on $n$ vertices is denoted by $P_{n}$. If in addition $v_{k}=v_{0}$ and $k=n$ then it is called a cycle of length $n, C_{n}$. If the edges $e_{1}, e_{2}, \ldots, e_{k}$ of the walk are distinct, it is called a trail. A graph $G$ is connected if for every $u, v \in V$, there exists a $u-v$ path. If $G$ is not connected, then it is disconnected. A connected acyclic graph is called a tree.

Definition 1.1.6. The distance between two vertices $u$ and $v$ of a connected graph $G$, denoted by $d(u, v)$, is the length of a shortest $u-v$ path in $G$. The eccentricity of a vertex $u, e(u)=\max \{d(u, v) / v \in V(G)\}$. The radius, $r(G)$ and the diameter, $\operatorname{diam}(\mathrm{G})$ are respectively the minimum and the maximum of the vertex eccentricities. For a vertex $u \in V(G)$, if there exists a vertex $v \in V(G)$ such that $d(u, v)=\operatorname{diam}(\mathrm{G}), v$ is then called a diametral vertex of $u$.

Definition 1.1.7. The complete graph $K_{n}$ is a graph of order $n$ in which each pair of distinct vertices is joined by an edge. A clique is a maximal complete subgraph.

Definition 1.1.8. A graph $G$ is bipartite if the vertex set can be partitioned into two non-empty sets $U$ and $U^{\prime}$ such that
every edge of $G$ has one end vertex in $U$ and the other in $U^{\prime}$. A bipartite graph in which each vertex of $U$ is adjacent to every vertex of $U^{\prime}$ is called a complete bipartite graph.

Definition 1.1.9. Let $G$ be a graph. The complement of $G$, denoted by $G^{c}$, is the graph with the same vertex set as $G$ and any two vertices are adjacent in $G^{c}$ if they are not adjacent in $G . K_{n}^{c}$ is called a totally disconnected graph.

Definition 1.1.10. For a graph $G$, a subset $V^{\prime}$ of $V(G)$ is a $k$-vertex cut of $G$ if the number of components in $G-V^{\prime}$ is greater than that of $G$ and $\left|V^{\prime}\right|=k$. The vertex connectivity of a graph $G, \kappa(G)$, is the least number of vertices whose deletion from $G$ increases the number of components of $G$. A graph $G$ is $k$-connected, if $\kappa(G) \geqslant k$. A vertex $v$ of $G$ is a cut vertex of $G$ if $\{v\}$ is a vertex cut of $G$. The edge connectivity of a graph $G, \kappa^{\prime}(G)$, is the least number of edges whose deletion from $G$ increases the number of components of $G$.

Definition 1.1.11. A set $S \subseteq V(G)$ of vertices in a graph $G$ is called a dominating set, if every $v \in V(G)$ is either an element of $S$ or is adjacent to an element of $S$. The domination number of a graph $G, \gamma(G)$, is the minimum cardinality
of a dominating set in $G$. A dominating set $S$ is a connected dominating set if $\langle S\rangle$ is a connected subgraph of $G$ and the corresponding domination number is the connected domination number, $\gamma_{c}(G)$.

## Illustration:

Fig 1.1: $\gamma\left(P_{4}\right)=\gamma_{c}\left(P_{4}\right)=2$ and $\gamma\left(P_{5}\right)=2, \gamma_{c}\left(P_{5}\right)=3$.

Definition 1.1.12. [25],[38] Edge critical graphs are graphs in which domination number decreases upon the addition of any missing edge while vertex critical graphs are graphs in which domination number decreases when any vertex is removed. A graph $G$ is $k-\gamma$ - edge critical if $\gamma(G)=k$ and $\gamma(G+e)<k$ for each $e \notin E(G)$ and $G$ is $k-\gamma$ - vertex critical if $\gamma(G)=k$ but for each vertex $v \in V(G), \gamma(G-v)<k$. Also, $G$ is $k-\gamma_{c}$ - edge critical if $\gamma_{c}(G)=k$ and $\gamma_{c}(G+e)<k$ for each $e \notin E(G)$ and $G$ is $k-\gamma_{c}$ - vertex critical if $\gamma_{c}(G)=k$ but for each vertex $v \in V(G), \gamma_{c}(G-v)<k$.

## Illustration:

Fig 1.2: $\gamma(G)=3, \gamma(G+e)=2$ and $\gamma(G-v)=2$.

Fig 1.3: $\gamma_{c}(G)=3, \gamma_{c}(G+e)=2$ and $\gamma_{c}(G-v)=2$.

Definition 1.1.13. [13] A graph $G$ is diameter minimal if $\operatorname{diam}(G-e)>\operatorname{diam}(G)$ for any $e \in E(G)$ and $G$ is diameter maximal if $\operatorname{diam}(G+e)<\operatorname{diam}(G)$ for any $e \notin E(G)$.

## Illustration:

Fig 1.4: $C_{5}$ is a diameter minimal graph and $P_{5}$ is a diameter maximal graph.

Definition 1.1.14. [36] The Cartesian product of two graphs $G$ and $H$, denoted by $G \square H$, is the graph with vertex set $V(G) \times V(H)$ and two vertices $\left(u_{1}, v_{1}\right),\left(u_{2}, v_{2}\right)$ are adjacent if either $u_{1}=u_{2}$ and $v_{1}-v_{2} \in E(H)$ or $u_{1}-u_{2} \in E(G)$ and $v_{1}=v_{2}$. The graph $P_{n} \square P_{m}$ is called the $\mathbf{n} \times \mathbf{m}$ grid graph. The graph $P_{n} \square C_{m}$ is called a cylinder and the graph $C_{n} \square C_{m}$ is called a torus.

## Illustration:

Fig 1.5: (i) $P_{4} \square P_{3}-\operatorname{grid}\left(\right.$ ii) $P_{4} \square C_{4}$ - cylinder (iii) $C_{4} \square C_{4}$ torus.

Definition 1.1.15. [36] The strong product of two graphs $G$ and $H$, denoted by $G \boxtimes H$, is the graph with vertex set $V(G) \times V(H)$ and two vertices $\left(u_{1}, v_{1}\right)$ and $\left(u_{2}, v_{2}\right)$ are adjacent if either $u_{1}=u_{2}$ and $v_{1}-v_{2} \in E(H)$ or $u_{1}-u_{2} \in E(G)$ and $v_{1}=v_{2}$ or $u_{1}-u_{2} \in E(G)$ and $v_{1}-v_{2} \in E(H)$.

Definition 1.1.16. [36] The lexicographic product of two graphs $G$ and $H$, denoted by $G \circ H$, is the graph with vertex set $V(G) \times V(H)$ and the two vertices $\left(u_{1}, v_{1}\right),\left(u_{2}, v_{2}\right)$ are adjacent if either $u_{1}-u_{2} \in E(G)$ or $u_{1}=u_{2}$ and $v_{1}-v_{2}$ $\in E(H)$.

## Illustration:

Fig 1.6: (i) $P_{4} \square P_{3}$
(ii) $P_{4} \boxtimes P_{3}$ (iii) $P_{4} \circ P_{3}$.

Definition 1.1.17. [43] Let $G * H$ be any of the graph products. For any vertex $g \in G$, the subgraph of $G * H$ induced by $\{g\} \times V(H)$ is called the $\mathbf{H}$ - layer at $g$ and denoted by ${ }^{g} H$. For any vertex $h \in H$, the subgraph of $G * H$ induced by $V(G) \times\{h\}$ is called the $\mathbf{G}$ - layer at $h$ and denoted by $G^{h}$.

Definition 1.1.18. [43] A hypercube of dimension $n$,
denoted by $Q_{n}$, is the graph whose vertex set consists of all 0 1 vectors $\left(v_{1}, v_{2}, \ldots, v_{n}\right)$, where two vertices are adjacent if they differ in precisely one coordinate.

Equivalently, $Q_{1}=K_{2}$ and $Q_{n}=Q_{n-1} \square K_{2}$ for $n \geqslant 2$.

Definition 1.1.19. [43] A graph $G$ is a Hamming graph if there exist integers $k, n_{1}, n_{2}, n_{3}, \ldots, n_{k-1}, n_{k}$ such that $G \cong K_{n_{1}} \square K_{n_{2}} \square \ldots \square K_{n_{k}}$, the vertex set of $G$ is the set of $k$ tuples $\left(i_{1}, i_{2}, \ldots, i_{k}\right)$, where $i_{j} \in\left\{1,2, \ldots, n_{j}\right\}$ and two $k$-tuples are adjacent if they differ in exactly one coordinate.

Definition 1.1.20. [46] Let $A$ be a family of connected graphs. If a graph $G$ has a spanning subgraph $H$ such that each component of $H$ is in $A$ then $H$ is called an $A$-factor or component factor of $G$.

## Illustration:

Fig 1.7: A graph $G$ with a $C_{4}$-factor.

Note: $G$ has a $\left\{K_{2}, P_{4}, K_{1,3}\right\}$ - factor also.

Definition 1.1.21. [41] For every integer $w: 1 \leqslant w \leqslant \delta(G)$, a $w$-container between any two distinct vertices $u$ and $v$ of $G$ is a set of $w$ internally vertex disjoint paths between them. Let $C_{w}(u, v)$ denote a $w$-container between $u$ and $v$. In $C_{w}(u, v)$, the parameter $w$ is the width of the container. The length of the container is the longest path in $C_{w}(u, v)$. The $w$-wide diameter of $G, D_{w}(G)$ is the minimum number $l$ such that there is a $C_{w}(u, v)$ of length $l$ between any pair of distinct vertices $u$ and $v$.

## Illustration:

G

Fig 1.8: For the graph $G, C_{2}(u, v)$ are
$\{u-c-v, u-a-b-v\},\{u-c-v, u-a-v\},\{u-v, u-a-b-v\}$, $\{u-v, u-a-v\},\{u-v, u-c-v\}$ and $D_{2}(G)=3$.

### 1.2 Notations

The diameter of a graph can be affected by the addition or the deletion of some edges. The following notations are used to describe the diameter variability [63].
$D^{-k}(G)$ : The minimum number of edges to be added to $G$ to decrease the diameter of $G$ by (at least) $k$, where $k \geqslant 1$. $D^{k}(G)$ : The minimum number of edges to be deleted from $G$ to increase the diameter of $G$ by (at least) $k$, where $k \geqslant 1$. $D^{0}(G)$ : The maximum number of edges to be deleted from $G$ without an increase in the diameter of $G$.

## Illustration:

G

Fig 1.9: $D^{-1}(G)=1$ (by adding the edge $d-f$ ). $D^{1}(G)=1$ (by deleting the edge $a-b$ ). $D^{0}(G)=3$, (by deleting the edges $a-i, c-e$, and $\left.d-e\right)$.

Vulnerability is a measure of the ability of the system to withstand vertex or edge faults and maximum routing delay. Diameter can be used to evaluate the maximum delay in routing. In this context, the following concepts are studied. The notations used are,
$f(G)=\max \{\operatorname{diam}(G-S) / S \subseteq V(G),|S|=\kappa(G)-1\}$ (called fault diameter [48]) and $f^{\prime}(G)=\max \left\{\operatorname{diam}(G-F) / F \subseteq E(G),|F|=\kappa^{\prime}(G)-1\right\}$.

## Illustration:

Fig 1.10: $\operatorname{diam}(\mathrm{G})=2, \kappa(G)=3$ and $f(G)=4(S=\{a, c\})$.
Also, $\kappa^{\prime}(G)=3$ and $f^{\prime}(G)=3(F=\{u-w, a-w\})$.

### 1.3 Basic properties and theorems

Product graphs have many interesting algebraic and other properties. The Cartesian product and strong product are commutative and associative. The lexicographic product is associative but not commutative. It is interesting to see that even if the factors $G$ and $H$ of a product graph have a property ' $P$ ' then it is not necessary that the product $G * H$ also has that property, where $*$ denotes any of the graph products mentioned above. As a case, $C_{m} \square C_{n}$ is non planar and $G \square H$ need not be Hamiltonian even if both $G$ and $H$ are Hamiltonian.

The Cartesian product is the most prominent graph product. The Cartesian product $G \square H$ can be obtained from $G$ by substituting a copy $H_{g}$ of $H$ for any vertex $g$ of $G$ and by joining the corresponding vertices of $H_{g}$ with $H_{g}^{\prime}$ if $g-g^{\prime} \in E(G)$. The Cartesian product of two connected graphs is a subgraph of both strong and lexicographic product of graphs. Hypercubes and Hamming graphs are important classes of the Cartesian product.

The lexicographic product $G \circ H$ can be obtained from $G$
by substituting a copy $H_{g}$ of $H$ for any vertex $g$ of $G$ and then joining all the vertices of $H_{g}$ with all the vertices of $H_{g}^{\prime}$ if $g-g^{\prime} \in E(G)$.

The following results are of interest to us.
Theorem 1.3.1. [43] A Cartesian product $G \square H$ is connected if and only if both factors are connected.

Theorem 1.3.2. [43] For any two connected graphs $G$ and $H$, $\operatorname{diam}(G \square H)=\operatorname{diam}(G)+\operatorname{diam}(H)$.

Theorem 1.3.3. [60] Let $G$ and $H$ be graphs on at least two vertices. Then $\kappa(G \square H)=\min \{\kappa(G)|V(H)|, \kappa(H)|V(G)|, \delta(G)+$ $\delta(H)\}$.

Theorem 1.3.4. [67] Let $G$ and $H$ be graphs on at least two vertices. Then $\kappa^{\prime}(G \square H)=\min \left\{\kappa^{\prime}(G)|V(H)|, \kappa^{\prime}(H)|V(G)|, \delta(G)+\right.$ $\delta(H)\}$.

Theorem 1.3.5. [36] If $G$ and $H$ are connected nontrivial, then $\kappa^{\prime}(G \square H)=\kappa^{\prime}(G)+\kappa^{\prime}(H)$ if and only if either $\kappa^{\prime}(G)=\delta(G)$ and $\kappa^{\prime}(H)=\delta(H)$, or one factor is complete and $\kappa^{\prime}=1$ for the other factor.

Theorem 1.3.6. [62] For all graphs $G$ and $H$,
$\gamma(G \square H) \leqslant \min \{\gamma(G)|V(H)|, \gamma(H)|V(G)|\}$.

Theorem 1.3.7. [29] For all graphs $G$ and $H$, $\gamma(G \square H) \geqslant \min \{|V(G)|,|V(H)|\}$.

Theorem 1.3.8. [36] A strong product $G \boxtimes H$ is connected if and only if both factors are connected.

Theorem 1.3.9. [36] For any two connected graphs $G$ and $H$, $\operatorname{diam}(G \boxtimes H)=\max \{\operatorname{diam}(G), \operatorname{diam}(H)\}$.

Theorem 1.3.10. [36] Let $G$ and $H$ be connected graphs, at lest one is not complete. Then $\kappa(G \boxtimes H)=\min \{\kappa(G)|V(H)|, \kappa(H)$ $|V(G)|, \ell(G \boxtimes H)\}$, where $\ell(G \boxtimes H)$ is the minimum size of a 7- set of $G \boxtimes H$ (if a separating set $S$ has an empty intersection with at least one $G$-layer and with at least one $H$ - layer, then $S$ is a 7- set of $G \boxtimes H)$.

Theorem 1.3.11. [36] Let $G$ be not complete. Then
$\kappa\left(G \boxtimes K_{n}\right)=n \kappa(G)$.

Theorem 1.3.12. [7] Let $G$ and $H$ be connected graphs. Then $\kappa^{\prime}(G \boxtimes H)=\min \left\{\kappa^{\prime}(G)(|V(H)|+2|E(H)|), \kappa^{\prime}(H)(|V(G)|+\right.$ $2|E(G)|), \delta(G \boxtimes H)\}$.

Theorem 1.3.13. [36] A lexicographic product $G \circ H$ is connected if and only if $G$ is connected.

Theorem 1.3.14. [36] If $G$ is not complete, then $\operatorname{diam}(G \circ H)=\operatorname{diam}(G)$ and $\operatorname{diam}\left(K_{n} \circ G\right)=2$

Theorem 1.3.15. [36] If $G$ is not complete and $H$ is any graph, then $\kappa(G \circ H)=\kappa(G)|V(H)|$.

Theorem 1.3.16. [36] For any graph $H, \kappa\left(K_{n} \circ H\right)=\kappa(H)+$ $(n-1)|V(H)|$.

Theorem 1.3.17. [68] Let $G$ and $H$ be two non-trivial graphs, and $G$ is connected. Then $\kappa^{\prime}(G)=\min \left\{\kappa^{\prime}\left(H_{1}\right) n_{2}^{2}, \delta\left(H_{2}\right)+\right.$ $\left.\delta\left(H_{1}\right) n_{2}\right\}$.

### 1.4 A survey of results

This section is a survey of results related to ours.

In [34], Graham and Harary showed that $D^{-1}\left(Q_{n}\right)=2$, $D^{1}\left(Q_{n}\right)=n-1$ and $D^{0}\left(Q_{n}\right) \geqslant(n-3) 2^{n-1}+2$. In [12], Bouabdallah et al. obtained the following bound, $(n-2) 2^{n-1}-\binom{n}{n / 2\rfloor}+2 \leqslant$ $D^{0}\left(Q_{n}\right) \leqslant(n-2) 2^{n-1}-\left\lceil 2^{n}-1 /(2 n-1)\right\rceil+1$. In [63], J. J. Wang et al. showed that $D^{-1}\left(C_{m} \square C_{n}\right)=2$, for $m \geqslant 12$, $D^{1}\left(C_{m} \square C_{n}\right)=2$ or 3 and $D^{0}\left(C_{m} \square C_{n}\right) \geqslant\left\{\begin{array}{l}m n-2 n+1 \\ m n-2 n\end{array}\right.$ when $m$ is
even and odd respectively. This notion is also discussed in [53].

One of the interesting results of diameter minimal graphs of diameter two in [31], is that every graph $G$ can be embedded as an induced subgraph in a diameter minimal graph of diameter two. In [57], Ore O. proved that a graph $G$ is diameter maximal if and only if
(1) $G$ has a unique pair of eccentric peripheral vertices $u$ and $v$.
(2) the set of vertices at each distance $k$ from $u$ induces a complete graph.
(3) every vertex at distance $k$ is adjacent to every vertex at distance $k+1$.

Also, a disconnected graph is diameter maximal if and only if $G=K_{m} \cup K_{n}$.

The problem of determining diameter vulnerability of a graph was proposed by Chung and Garey [23]. The problem is proved to be NP-complete by Schoone et al. [59]. In [58] Peyrat show that $3 \sqrt{2 t}-3<f^{\prime}(G) \leqslant 3 \sqrt{2 t}+4$ where $G$ is a $(t+1)$ - connected graph of diameter 3. In [69] H.X. Ye et al. improves the result of Peyrat and gave a bound as $4 \sqrt{2 t}-6<f^{\prime}(G) \leqslant$ $\max \{59,5 \sqrt{2 t}+7\}$ for $t \geqslant 4$. This notion is also discussed in
[55], [9] and [14]. The concept of fault diameter was introduced by M.S. Krishnamoorthy and B. Krishnamurthy [48]. This notion is also discussed in [32] and [49]. The wide diameter of some networks is studied in [52].

In [2], Ando et al. proved that a connected claw-free graph $G$ with $\delta(G) \geqslant d$ has a path factor having each path of length at least $d$. Also, they conjectured that a 2-connected claw-free graph $G$ with $\delta(G) \geqslant d$ has a path factor of length at least $3 d+2$. In [15], Cada proved the conjecture for line graphs. In [3], Armen et al. showed that a simple $(3,4)$-biregular bigraph always has a path factor such that the endpoints of each path have degree three. In [44], Kaneko showed that every cubic graph has a path factor such that each component is a path of length 2,3 or 4 . It was shown in [47], that a 2-connected cubic graph has a path factor whose components are paths of length 2 or 3 . In [46], Kano et al. proved that if a graph G satisfies iso $(\mathrm{G}-\mathrm{S}) \leqslant|S| / 2$ for all $S \subseteq V(G)$, then G has a $\left\{K_{1,2}, K_{1,3}, K_{5}\right\}$-factor where iso(G-S) denotes the number of isolated vertices in $G-S$. Some results on different types of path factors can be found in [28], [45], [51]. Hell and Kirkpatrick [39], [40] proved that if $A$ is a graph on at least 3 vertices, then deciding whether $G$ has a
$A$-factor is NP-complete.

The connected dominating set has attracted interest due to its applications in network routing. In [17], Y.C. Chen and Y.L Syu showed that for an $n$-dimensional Star graph $Q_{n}$ and $n$ dimensional Star graph $S_{n}$, the order of minimum connected dominating set (MCDS), $\left|\operatorname{MCDS}\left(Q_{n}\right)\right| \leqslant 2^{n-2}+2$ where $n \geqslant 3$ and $\left|\operatorname{MCDS}\left(S_{n}\right)\right| \leqslant 2(n-1)$ ! where $n \geqslant 3$. In [61], Sumner et al. characterized $2-\gamma$ - edge critical graphs and proved that the disconnected 3- $\gamma$ - edge critical graphs are the disjoint union of $2-\gamma$ - edge critical graphs and a complete graph. For $k \geqslant 4$, the characterization of connected $k-\gamma$ - edge critical graphs is not known. In [16], Chen et al. gave a characterization of $2-\gamma_{c}$ - edge critical graphs. Also, if $G$ is $3-\gamma_{c}$ - edge critical then either $G$ is isomorphic to $C_{5}$ or contains a triangle and that if $G$ is $3-\gamma_{c}$ - edge critical of even order then $G$ contains a one factor. In [8], Brigham et al. gave a characterization of $2-\gamma$ - vertex critical graphs. But for $k \geqslant 3$, only some properties of $k-\gamma$ - vertex critical graphs are known and there is no characterization of such graphs. In [30], Flandrin et al. studied some properties of 3- $\gamma$ - edge critical graphs and proves that if $G$ is a 3- $\gamma$ - edge critical connected graph of order $n$
with $\delta \geqslant 2$, then $G$ is 1-tough and circumference of $G$ is at least $n-1$. Some properties of $3-\gamma_{c}$ - vertex critical graphs are discussed in [1]. For $k \geqslant 4$, no characterization of $k-\gamma_{c}$ - vertex critical graphs are known. In [33], Goncalves et al. studied the domination number of grids.

We shall discuss these notions in product graphs in this thesis. In this thesis, we consider the graphs $H_{1}, H_{2}$ and denote the $V\left(H_{1}\right)=\left\{u_{1}, u_{2}, \ldots, u_{n_{1}}\right\}, V\left(H_{2}\right)=\left\{v_{1}, v_{2}, \ldots, v_{n_{2}}\right\}$ and $V\left(H_{1} * H_{2}\right)=\left\{u_{1} v_{1}, u_{1} v_{2}, \ldots, u_{n_{1}} v_{n_{2}}\right\}$ where $* \in\{\square, \boxtimes, \circ\}$. Also, $\left|E\left(H_{1}\right)\right|=m_{1}$ and $\left|E\left(H_{2}\right)\right|=m_{2}$. Since, $H_{1} * K_{1} \cong H_{1}$ we assume that $H_{1}, H_{2} \neq K_{1}$.

### 1.5 Summary of the thesis

This thesis entitled 'Studies on some topics in product graphs' is divided into five chapters including an introductory chapter giving a brief history of graph theory, basic definitions and results which we have used in our work.

In the second chapter the diameter variability of product
graphs is studied in detail. The main results in this chapter are:
$\star$ Let $G \cong H_{1} \square H_{2}$. Then $D^{0}(G) \geqslant 2$.

* Let $G \cong H_{1} \square H_{2}$. Then $D^{1}(G)=1$ if and only if $H_{1}$ is a complete graph and either $H_{2}$ has at least one pair of vertices with exactly one diametral path $P$ and no path of length $\operatorname{diam}\left(H_{2}\right)+1$ which is edge disjoint with $P$ or there exist an edge in $H_{2}$ that is on all paths of length $\operatorname{diam}\left(H_{2}\right)$, $\operatorname{diam}\left(H_{2}\right)+1$ between any two diametral vertices in $H_{2}$.
$\star$ Let $G \cong H_{1} \square H_{2}$.
(a) If both $H_{1}$ and $H_{2}$ are complete graphs with $n_{1}, n_{2}>2$, then $D^{1}(G)=2$.
(b) If $H_{1}$ is a complete graph and $H_{2}$ is a not complete graph, then $D^{1}(G) \leqslant \delta\left(H_{2}\right)$.
(c) If both $H_{1}$ and $H_{2}$ are not complete graphs, then $D^{1}(G) \leqslant \Delta(G)-1$.
$\star$ Let $G \cong H_{1} \square H_{2}$. Then $D^{-1}(G)=1$ if and only if $G$ is any one of the following graphs where,
(a) $H_{1}$ is a complete graph and $H_{2}$ is a not complete graph with $D^{-2}\left(H_{2}\right)=1$.
(b) $H_{1}$ is a not complete graph with a universal vertex or there exist a vertex in $H_{1}$ that is on at least one path between any two diametral vertices and $H_{2}$ is a not complete graph with $D^{-1}\left(H_{2}\right)=1$.
$\star$ Let $G \cong H_{1} \boxtimes H_{2}$. Then $D^{0}(G) \geqslant 6$.
$\star$ Let $G \cong H_{1} \boxtimes H_{2}$. Then $D^{1}(G)=1$ if and only if $G$ is any one of the following graphs where,
(a) both $H_{1}$ and $H_{2}$ are complete graphs.
(b) $H_{1}$ and $H_{2}$ are not complete graphs with $\operatorname{diam}\left(H_{1}\right)=$ $\operatorname{diam}\left(H_{2}\right)$ and either $H_{1}$ or $H_{2}$ have at least one pair of vertices with exactly one diametral path or there exist an edge in $H_{1}$ or $H_{2}$ that is on all diametral paths between any two vertices.
$\star$ Let $G \cong H_{1} \boxtimes H_{2}$. Then $D^{1}(G) \leqslant \alpha\left(1+\delta\left(H_{2}\right)\right)$ where $\alpha$ is the minimum number of edge disjoint paths of length $\operatorname{diam}\left(H_{1}\right)$ between any two vertices in $H_{1}$.
$\star$ Let $G \cong H_{1} \boxtimes H_{2}$ be connected graph. Then $D^{-1}(G)=1$ if and only if $H_{2}$ has a universal vertex and $H_{1}$ is a connected graph with $\operatorname{diam}\left(H_{1}\right) \geqslant 4$ and $D^{-2}\left(H_{1}\right)=1$ when an edge is added between a diametral vertex and any other vertex
of $H_{1}$ and $D^{-1}\left(H_{1}\right)=1$ when an edge is added between any two other vertices of $H_{1}$.
$\star$ Let $G \cong H_{1} \circ H_{2}$. Then $D^{0}(G) \geqslant 3$.
$\star$ Let $G \cong H_{1} \circ H_{2}$. Then $D^{1}(G)=1$ if and only if $G$ is any one of the following graphs where,
(a) both $H_{1}$ and $H_{2}$ are complete graphs.
(b) $H_{1}=K_{2}$ or a connected graph with diameter two in which there exist at least one pair of adjacent vertices with no path of length two between them and $H_{2}$ is a disconnected graph in which there exist at least one component with an isolated vertex.
$\star$ Let $G \cong H_{1} \circ H_{2}$. Then $D^{1}(G) \leqslant \alpha n_{2}$ where $\alpha$ is the minimum number of edge disjoint paths of length $\operatorname{diam}\left(H_{1}\right)$ between any two vertices in $H_{1}$.
$\star$ Let $G \cong H_{1} \circ H_{2}$. Then $D^{-1}(G)=1$ if and only if $G$ is any one of the following graphs where,
(a) $H_{2}$ has a universal vertex and $H_{1}$ is a connected graph with $\operatorname{diam}\left(H_{1}\right) \geqslant 4$ and $D^{-2}\left(H_{1}\right)=1$ when an edge is added between a diametral vertex and any other vertex of $H_{1}$.
(b) $H_{2}$ is any graph and $H_{1}$ is a connected graph with $\operatorname{diam}\left(H_{1}\right) \geqslant 4$ and $D^{-1}\left(H_{1}\right)=1$ when an edge is added between the diametral vertices or between any two other vertices of $H_{1}$.

In the third chapter we study the diameter vulnerability of three graph products. Following are some of the results obtained.

- Let $G \cong H_{1} \square H_{2}$, where $H_{1}$ is a complete graph and $H_{2}$ is a connected graph with $\kappa^{\prime}\left(H_{2}\right)=\delta\left(H_{2}\right)$. Then
$f^{\prime}(G)=\operatorname{diam}(G)+1$.
- Let $G \cong H_{1} \square H_{2}$ be a connected graph. Then
$f^{\prime}(G) \leqslant \max \left\{f^{\prime}\left(H_{1}\right)+2 \operatorname{diam}\left(H_{2}\right), f^{\prime}\left(H_{2}\right)+2 \operatorname{diam}\left(H_{1}\right)\right\}$.
- Let $G \cong H_{1} \boxtimes H_{2}$ be a connected graph. Then
$f^{\prime}(G) \leqslant \max \left\{f^{\prime}\left(H_{1}\right)+\operatorname{diam}\left(H_{2}\right), f^{\prime}\left(H_{2}\right)+\operatorname{diam}\left(H_{1}\right)\right\}$.
- Let $G \cong H_{1} \circ H_{2}$ be a connected graph where $n_{1}, n_{2} \geqslant 3$.

Then $f^{\prime}(G) \leqslant f^{\prime}\left(H_{1}\right)+\operatorname{diam}\left(H_{2}\right)$.

- Let $G \cong H_{1} \square H_{2}$ be a connected graph. Then
$f(G) \leqslant \max \left\{f\left(H_{1}\right)+2 \operatorname{diam}\left(H_{2}\right), f\left(H_{2}\right)+2 \operatorname{diam}\left(H_{1}\right)\right\}$.
- Let $G \cong H_{1} \circ H_{2}$ be a connected graph. Then $f(G) \leqslant \max \left\{f\left(H_{1}\right), f\left(H_{2}\right)\right\}$.
- Let $G \cong H_{1} \boxtimes H_{2}$ be a connected graph. Then

$$
f(G) \leqslant \max \left\{f\left(H_{1}\right)+\operatorname{diam}\left(H_{2}\right), f\left(H_{2}\right)+\operatorname{diam}\left(H_{1}\right)\right\} .
$$

- For any two connected graphs $H_{1}$ and $H_{2}$,

Wide diameter $\left(H_{1} \circ H_{2}\right)=$ Wide diameter $\left(H_{1}\right)$.

The fourth chapter is the study of the component factors of the product graphs. Some of the results obtained are:
$\bowtie$ Let $G \cong H_{1} \square H_{2}$ be a connected graph where $\left|H_{1}\right|=n_{1}$ and $\left|H_{2}\right|=n_{2}$. Then $G$ has a $C_{4}$-factor if and only if $G$ is any one of the following graphs where,
((I) $H_{1}$ or $H_{2}$ has a $C_{4}$-factor.
(II) both $H_{1}$ and $H_{2}$ have no $C_{4}$-factor and,
(a) both $H_{1}$ and $H_{2}$ are complete graphs with $n_{1}, n_{2}$ even and $n_{1}, n_{2} \not \equiv 0 \bmod 4$.
(b) $H_{1}$ is a complete graph with $n_{1}$ even and $H_{2}$ is a not complete graph with $n_{2}$ even, has at least one vertex with at most one pendant vertex attached to it and has a $\left\{K_{1,1}\right\}$-factor.
(c) $H_{1}$ and $H_{2}$ are not complete graphs with $n_{1}, n_{2}$ even, both have at least one vertex with at most one pendant vertex attached to it and have a $\left\{K_{1,1}\right\}$-factor.
$\bowtie$ Let $G \cong K_{n_{1}} \square K_{n_{2}}$ where $n_{1}, n_{2} \geqslant 2$. Then $G$ has a $\left\{K_{1,2}, C_{4}\right\}$-factor.
$\bowtie$ Let $G \cong K_{n_{1}} \square H_{2}$ be a connected graph where $H_{2}$ is a not complete graph. Then $G$ has a $\left\{K_{1,1}, K_{1,2}, C_{4}\right\}$-factor.
$\bowtie$ Let $G \cong H_{1} * H_{2}$ where $* \in\{\square, \boxtimes, \circ\}$ and $H_{1}, H_{2}$ are connected graphs. Then $G$ has a $\left\{K_{1, n}, C_{4}\right\}$-factor where $n \leqslant t$ and $t$ is the maximum degree of an induced subgraph $K_{1, t}$ in $H_{1}$ or $H_{2}$.
$\bowtie$ The hypercube $Q_{n}$ has a $\left\{P_{4}\right\}$-factor.
$\bowtie$ A Hamming graph has a $\left\{P_{3}, P_{4}\right\}$-factor.

The domination criticality is discussed in the last chapter. The main results are listed below.
$\oplus$ Let $G \cong H_{1} \square H_{2}$ be a connected graph. Then $\gamma(G)=2$ if and only if $H_{1}=K_{2}$ and $H_{2}$ is either a $C_{4}$ or has a universal vertex.
$\oplus$ Let $G \cong H_{1} \square H_{2}$ be a connected graph. Then
$\gamma_{c}(G)=\gamma(G)=2$ if and only if $H_{1}=K_{2}$ and $H_{2}$ has a universal vertex.

Let $G \cong H_{1} \square H_{2}$ be a connected graph. Then $G$ is $2-\gamma$ - vertex (edge) critical if and only if $G=C_{4}$.

Let $G \cong H_{1} \square H_{2}$ be a connected graph. Then $G$ is 2 - $\gamma_{c}$ - vertex (edge) critical if and only if $G=C_{4}$.

Let $G \cong H_{1} \square H_{2}$ be a connected graph. Then $\gamma(G)=3$ if and only if $G$ is any one of the following graphs where,
(a) $H_{1}=K_{3}$ or $P_{3}$ and $H_{2}$ has a universal vertex.
(b) $H_{1}=K_{2}$ and $H_{2}$ has a vertex of degree $n_{2}-2$.
(c) $H_{1}=K_{2}$ and $H_{2}$ has a vertex $v_{r}$ of degree $n_{2}-3$ and is not adjacent to the vertices $v_{p}$ and $v_{q}$ with $N\left[v_{p}\right] \cup N\left[v_{q}\right] \cup$ $\left\{v_{r}\right\}=V\left(H_{2}\right)$.
(d) $H_{1}=K_{3}$ or $P_{3}$ and $H_{2}=C_{4}$.
$\oplus$ Let $G \cong H_{1} \square H_{2}$ be a connected graph. Then $\gamma_{c}(G)=\gamma(G)=3$ if and only if $H_{1}=K_{3}$ or $P_{3}$ and $H_{2}$ has a universal vertex.

Let $G \cong H_{1} \square H_{2}$ be a connected graph. Then $G$ is

3- $\gamma$ - vertex (edge) critical if and only if $H_{1}=H_{2}=K_{3}$.
$\oplus$ Let $G \cong H_{1} \square H_{2}$ be a connected graph. Then $G$ is
3- $\gamma_{c}$ - vertex (edge) critical if and only if $H_{1}=H_{2}=K_{3}$.

Some results of this thesis are included in [18] - [22]. The thesis is concluded with some suggestions for further study and a bibliography.

## Chapter 2

## Diameter variability of the product graphs

The diameter of a graph can be affected by the addition or the deletion of edges. In this chapter we examine the product graphs whose diameter increases (decreases) by the deletion (addition) of a single edge. The problems of minimality and maximality of the product graphs with respect to its diameter are also solved. These problems are motivated by the fact that most of the graph products are good interconnection networks and a good network must be hard to disrupt and the transmis-

[^0]sions must remain connected even if some vertices or edges fail.

### 2.1 Diameter variability of the Cartesian product of graphs

If both $H_{1}$ and $H_{2}$ are $K_{2}$ 's, then $G$ is $C_{4}$ and the deletion of any edge increases the diam(G).

Theorem 2.1.1. Let $G \cong H_{1} \square H_{2}$. Then $D^{0}(G) \geqslant 2$.

Proof. We shall prove the theorem by showing that there exist at least two edges in $G$ that can be deleted without an increase in the diam(G) by considering the following three cases.

Case 1: $H_{1}$ and $H_{2}$ are complete graphs where $n_{1}$ or $n_{2}>2$.

Suppose that both $n_{1}, n_{2}>2$.
Let the two edges $u_{i} v_{p}-u_{i} v_{q}$ and $u_{j} v_{r}-u_{x} v_{r}$ where
$i \neq j \neq x \in\left\{1,2, \ldots, n_{1}\right\}$ and $p \neq q \neq r \in\left\{1,2, \ldots, n_{2}\right\}$, be deleted. There are paths of length two between $u_{i} v_{p}, u_{i} v_{q}$ and $u_{j} v_{r}, u_{x} v_{r}$ in $G$. Now, consider the vertices whose diametral path contain the deleted edges. The distance between these vertices remains the same, since $\delta(G) \geqslant 4$ there is an alternate path

### 2.1. Diameter variability of the Cartesian product of graphs 39

of length $\operatorname{diam}(\mathrm{G})$ through the neighbours of the deleted edge. Also, the distance between any two other vertices is not affected by the removal of these two edges.

Suppose that $n_{1}=2$ and $n_{2}>2$. Let the two edges $u_{1} v_{p}-u_{1} v_{q}$ and $u_{2} v_{q}-u_{2} v_{r}$ where $p \neq q \neq r \in\left\{1,2, \ldots, n_{2}\right\}$, be deleted. There are paths of length two between these pairs of vertices. Also, the distance between any two other vertices is not affected by the removal of these two edges. Thus, the diam $(\mathrm{G})$ remains the same.

Case 2: $H_{1}$ and $H_{2}$ are not complete graphs.

Let the two edges $u_{i} v_{p}-u_{i} v_{q}$ and $u_{j} v_{r}-u_{x} v_{r}$ where
$i \neq j \neq x \in\left\{1,2, \ldots, n_{1}\right\}$ and $p \neq q \neq r \in\left\{1,2, \ldots, n_{2}\right\}$, be deleted. There is a path $u_{i} v_{p}-u_{y} v_{p}-u_{y} v_{q}-u_{i} v_{q}$ of length three between $u_{i} v_{p}$ and $u_{i} v_{q}$. Similarly, $d\left(u_{j} v_{r}, u_{x} v_{r}\right) \leqslant 3$. Now, consider the vertices whose diametral path contain the deleted edges. The distance between these vertices remains the same, since $\delta(G) \geqslant 2$ there is an alternate path of length $\operatorname{diam}(\mathrm{G})$ through the neighbours of the deleted edge. Thus, the diam(G) remains the same.

Case 3: $H_{1}$ is a complete graph and $H_{2}$ is a not complete graph.

Let the two edges $u_{i} v_{p}-u_{j} v_{p}$ and $u_{i} v_{q}-u_{j} v_{q}$ where $i \neq j \in\left\{1,2, \ldots, n_{1}\right\}$ and $v_{p}$ is not adjacent to $v_{q}$ in $H_{2}, p, q \in$ $\left\{1,2, \ldots, n_{2}\right\}$, be deleted. There is a path of length at most three between these pairs of vertices. Therefore, $d\left(u_{i} v_{p}, u_{i} v_{q}\right) \leqslant 3$ and $d\left(u_{i} v_{q}, u_{j} v_{q}\right) \leqslant 3$. Also, the distance between any two other vertices is not affected by the removal of these two edges. Thus, the diam(G) remains the same.

Hence, there exist at least two edges in $G$ that can be deleted without an increase in the diam(G).

Theorem 2.1.2. Let $G \cong H_{1} \square H_{2}$. Then $D^{0}(G)=2$ if and only if $G$ is any one of the graphs shown in Fig 2.1.

Fig 2.1: The graphs $G: D^{0}(G)=2$.

Proof. Suppose that $G$ is any one of the graphs shown in Fig 2.1, then by deleting the bold edges, it is clear that $D^{0}(G)=2$.

Conversely suppose that $D^{0}(G)=2$. We shall show that $G$ is precisely any one of the graphs in Fig 2.1.

Let $u_{x}, u_{y}$ be a pair of diametral vertices in $H_{1}$, by a path $u_{x}-u_{x+1}-u_{x+2}-\ldots-u_{y-1}-u_{y}$ and $v_{w}, v_{z}$ be a pair of diametral vertices in $H_{2}$, by a path $v_{w}-v_{w+1}-v_{w+2}-\ldots-v_{z-1}-v_{z}$.

Let $G \cong K_{n_{1}} \square K_{n_{2}}$ where $n_{1}, n_{2}>2$.

Let the three edges $u_{i} v_{p}-u_{i} v_{q}, u_{j} v_{q}-u_{j} v_{r}$ and $u_{x} v_{p}-u_{x} v_{r}$ where $i \neq j \neq x \in\left\{1,2, \ldots, n_{1}\right\}$ and $p \neq q \neq r \in\left\{1,2, \ldots, n_{2}\right\}$, be deleted. There is a path $u_{i} v_{p}-u_{i} v_{r}-u_{i} v_{q}$ of length two between $u_{i} v_{p}$ and $u_{i} v_{q}$ in $G$ and so $d\left(u_{i} v_{p}, u_{i} v_{q}\right)=2$. Similarly, $d\left(u_{j} v_{q}, u_{j} v_{r}\right)=d\left(u_{x} v_{p}, u_{x} v_{r}\right)=2$. Also, the distance between any two other vertices is not affected by the removal of these three edges. Thus, the diam $(\mathrm{G})$ remains the same.

Let $G \cong H_{1} \square H_{2}$, where $H_{1}$ and $H_{2}$ are not complete graphs.

Let the three edges $u_{i} v_{p}-u_{j} v_{p}, u_{i} v_{q}-u_{j} v_{q}$ and $u_{a} v_{p}-u_{a} v_{r}$ where $i \neq j \neq a \in\left\{1,2, \ldots, n_{1}\right\}$ and $v_{p}$ is not adjacent to $v_{q}$ in $H_{2}, p, q \neq r \in\left\{1,2, \ldots, n_{2}\right\}$, be deleted. There is a path of length at most three between these pairs of vertices. Now, $d\left(u_{x} v_{p}, u_{y} v_{p}\right) \leqslant \operatorname{diam}\left(H_{1}\right)+2$ by a path $u_{x} v_{p}-u_{x} v_{r}-u_{x+1} v_{r}-$
$\ldots-u_{y} v_{r}-u_{y} v_{p}$ where $d\left(u_{x} v_{p}, u_{x} v_{r}\right)=d\left(u_{y} v_{p}, u_{y} v_{r}\right)=1$ and $d\left(u_{x} v_{r}, u_{y} v_{r}\right) \leqslant \operatorname{diam}\left(H_{1}\right)$. Also, $d\left(u_{x} v_{q}, u_{y} v_{q}\right) \leqslant \operatorname{diam}\left(H_{1}\right)+2$ and $d\left(u_{a} v_{w}, u_{a} v_{z}\right) \leqslant \operatorname{diam}\left(H_{2}\right)+2$. Thus, the diam $(\mathrm{G})$ remains the same.

Hence, it is clear that at least one graph (say) $H_{1}$ should be a complete graph and $H_{2}$ is a not complete graph.

Let $G \cong K_{n_{1}} \square H_{2}$ where $n_{1}>2$.

Let the three edges $u_{i} v_{p}-u_{j} v_{p}, u_{j} v_{q}-u_{x} v_{q}$ and $u_{i} v_{r}-u_{x} v_{r}$ where $i \neq j \neq x \in\left\{1,2, \ldots, n_{1}\right\}$ and $p \neq q \neq r \in\left\{1,2, \ldots, n_{2}\right\}$, be deleted. There is a path $u_{i} v_{p}-u_{x} v_{p}-u_{j} v_{p}$ of length two between $u_{i} v_{p}$ and $u_{j} v_{p}$ in $G$. Similarly, $d\left(u_{j} v_{q}, u_{x} v_{q}\right)=d\left(u_{i} v_{r}, u_{x} v_{r}\right)=2$. Also, the distance between any two other vertices is not affected by the removal of these three edges. Thus, the diam(G) remains the same.

Hence, it follows that $n_{1} \leqslant 2$. Now, we will consider the different cases depending on the value of $n_{2}$.

Case 1: $G \cong K_{2} \square H_{2}$ where $H_{2}$ is a not complete graph with $n_{2} \geqslant 5$.

Suppose that $\operatorname{diam}\left(H_{2}\right) \geqslant 4$.
Consider a pair of diametral vertices $v_{w}$ to $v_{z}$ in $H_{2}$ where $v_{l}$ is a vertex in a diametral path between them and is not adjacent to both $v_{w}$ and $v_{z}$. Let the three edges $u_{1} v_{w}-u_{2} v_{w}, u_{1} v_{l}-u_{2} v_{l}$ and $u_{1} v_{z}-u_{2} v_{z}$, be deleted. There is a path of length three between these pairs of vertices. Consider the vertex $u_{1} v_{w}$ in $G$. Then $u_{2} v_{z}$, a diametral vertex of $u_{1} v_{w}$ is at a distance $\operatorname{diam}(\mathrm{G})$ by a path $u_{1} v_{w}-u_{1} v_{w+1}-\ldots-u_{1} v_{l-1}-u_{2} v_{l-1}-u_{2} v_{l}-\ldots-u_{2} v_{z}$. Thus, the diam(G) remains the same.

Suppose that $\operatorname{diam}\left(H_{2}\right)=3$.
Consider a pair of diametral vertices $v_{w}$ to $v_{z}$ in $H_{2}$ where $v_{b}$ is a vertex not in any of the diametral path between them in $\mathrm{H}_{2}$. Let the three edges $u_{1} v_{w}-u_{2} v_{w}, u_{1} v_{z}-u_{2} v_{z}$ and $u_{1} v_{b}-u_{2} v_{b}$, be deleted. There is a path of length at most four between these pairs of vertices. Thus, the diam(G) remains the same.

Suppose that $\operatorname{diam}\left(H_{2}\right)=2$.
Suppose that $H_{2}$ has a universal vertex $v_{p}$.

Let the three edges $u_{1} v_{q}-u_{2} v_{q}, u_{1} v_{r}-u_{2} v_{r}$ and $u_{1} v_{l}-u_{2} v_{l}$ where $q, r, l \neq p$, be deleted. There is a path of length at most three between these pairs of vertices. Thus, the diam $(\mathrm{G})$ remains
the same.

Suppose that $H_{2}$ does not have a universal vertex and $d\left(v_{w}, v_{z}\right)=2$ in $H_{2}$.

Let the three edges $u_{1} v_{w}-u_{2} v_{w}, u_{1} v_{z}-u_{2} v_{z}$ and $u_{1} v_{p}-u_{1} v_{q}$, be deleted. There is a path of length three between these pairs of vertices in $G$. Thus, the distance between any two other vertices is at most three.

Case 2: $G \cong K_{2} \square K_{n_{2}}$ where $n_{2} \geqslant 5$.

Let the three edges $u_{1} v_{2}-u_{1} v_{3}, u_{1} v_{2}-u_{1} v_{4}$ and $u_{1} v_{2}-u_{1} v_{5}$, be deleted. There are paths of length two between these pairs of vertices. Thus, the diam $(G)$ remains the same.

Thus, there exist at least three edges in $G$ that can be deleted without an increase in the diam(G). Hence, it follows that $n_{2} \leqslant 4$. Now, by an exhaustive verification of all graphs $H_{2}$ with $n_{2} \leqslant 4$, it follows that $G \cong K_{2} \square K_{3}, K_{2} \square P_{3}$ and $K_{2} \square P_{4}$.

Theorem 2.1.3. Let $G \cong H_{1} \square H_{2}$. Then $D^{1}(G)=1$ if and only if $H_{1}$ is a complete graph and either $H_{2}$ has at least one pair of

### 2.1. Diameter variability of the Cartesian product of graphs 45

vertices with exactly one diametral path $P$ and no path of length $\operatorname{diam}\left(H_{2}\right)+1$ which is edge disjoint with $P$ or there exist an edge in $H_{2}$ that is on all paths of length $\operatorname{diam}\left(H_{2}\right), \operatorname{diam}\left(H_{2}\right)+1$ between any two diametral vertices in $\mathrm{H}_{2}$.

Proof. Let $u_{x}, u_{y}$ be a pair of diametral vertices in $H_{1}$, by a path $u_{x}-u_{x+1}-u_{x+2}-\ldots-u_{y-1}-u_{y}$ and $v_{w}, v_{z}$ be a pair of diametral vertices in $H_{2}$, by a path $v_{w}-v_{w+1}-v_{w+2}-\ldots-$ $v_{z-1}-v_{z}$.

Suppose that $H_{1}$ is a complete graph. If $H_{2}$ has a pair of vertices $v_{w}, v_{z}$, with one diametral path $P$ and no path of length diam $\left(H_{2}\right)+1$ edge disjoint with $P$, then $v_{p}-v_{q}$ be an edge whose deletion increases the $\operatorname{diam}\left(H_{2}\right)$. If $H_{2}$ has a pair of vertices $v_{w}, v_{z}$, with paths of length $\operatorname{diam}\left(H_{2}\right), \operatorname{diam}\left(H_{2}\right)+1$ which are not edge disjoint with each other, then $v_{p}-v_{q}$ is a common edge in all these paths. Consider a pair of vertices $u_{i} v_{w}, u_{i} v_{z}$ in $G$. Let an edge $u_{i} v_{p}-u_{i} v_{q}$, be deleted from the path $u_{i} v_{w}-u_{i} v_{w+1} \ldots u_{i} v_{z}$ in $G$, then the $\operatorname{diam}(G)$ increases by a path $u_{i} v_{w}-u_{j} v_{w}-u_{j} v_{w+1}-u_{j} v_{w+2} \ldots u_{j} v_{z}-u_{i} v_{z}$ where $d\left(u_{j} v_{w}, u_{j} v_{z}\right)=\operatorname{diam}\left(H_{2}\right), d\left(u_{i} v_{w}, u_{j} v_{w}\right)=d\left(u_{i} v_{z}, u_{j} v_{z}\right)=1$. Also, $d\left(u_{i} v_{r}, u_{i} v_{s}\right) \leqslant \operatorname{diam}(\mathrm{G})$ where $r, s \in\left\{1,2, \ldots, n_{2}\right\}$. The
distance between any two other vertices is not affected by the removal of this edge.

Conversely suppose that $D^{1}(G)=1$. If both $H_{1}$ and $H_{2}$ are not complete graphs, then at least two edges should be deleted to increase the diam(G).

If $H_{1}$ and $H_{2}$ are complete graphs with $n_{1}, n_{2}>2$, there exist two internally vertex disjoint paths of length two between two non adjacent vertices $u_{i} v_{p}$ and $u_{j} v_{q}$ in $G$. Thus, at least two edges should be deleted to increase the diam(G).

Hence, it is clear that at least one graph (say) $H_{1}$ should be a complete graph and $H_{2}$ is a not complete graph.

Suppose that $d\left(u_{i} v_{w}, u_{i} v_{z}\right)=\operatorname{diam}\left(H_{2}\right)$. Let an edge $u_{i} v_{p}-u_{i} v_{q}$, be deleted.

If $H_{2}$ contains two internally edge disjoint paths, one of length $\operatorname{diam}\left(H_{2}\right)$ and the other of length $\operatorname{diam}\left(H_{2}\right)+1$ or two internally edge disjoint paths of length $\operatorname{diam}\left(H_{2}\right)$ between $v_{w}$ and $v_{z}$ in $H_{2}$, then the diam( G$)$ remains the same, since in both the cases there exist an alternate path of length $\operatorname{diam}\left(H_{2}\right)+1$ or $\operatorname{diam}\left(H_{2}\right)$ between $u_{i} v_{w}$ and $u_{i} v_{z}$ in $G$.

If $H_{2}$ has paths of length $\operatorname{diam}\left(H_{2}\right)$ and $\operatorname{diam}\left(H_{2}\right)+1$ between $v_{w}$ and $v_{z}$ in $H_{2}$, such that all these paths have some edges in common then, the $\operatorname{diam}(G)$ remains the same. Since, all these paths does not have a common edge (say) $v_{p}-v_{q}$, even if a delete an edge there exist an alternative path of length $\operatorname{diam}\left(H_{2}\right)+1$ or $\operatorname{diam}\left(H_{2}\right)$ between $u_{i} v_{w}$ and $u_{i} v_{z}$, without affecting the $\operatorname{diam}(G)$.

Hence, either $H_{2}$ has at least one pair of vertices with only one diametral path $P$ and no path of length $\operatorname{diam}\left(H_{2}\right)+1$ which is edge disjoint with $P$ or there exist an edge in $H_{2}$ that is on all paths of length $\operatorname{diam}\left(H_{2}\right), \operatorname{diam}\left(H_{2}\right)+1$ between any two diametral vertices in $\mathrm{H}_{2}$.

Corollary 2.1.4. $G \cong H_{1} \square H_{2}$ is diameter minimal if and only if $H_{1}=H_{2}=K_{2}$.

Proof. If $G=C_{4}$, then $G$ is diameter minimal.

Conversely suppose that $G$ is diameter minimal. In Theorem 2.1.3 we have characterized the Cartesian product of graphs whose diameter increases by the deletion of a single edge. Hence, we need to prove the theorem only for such $G \mathrm{~s}$.

Let $n_{1}>2$ and $n_{2} \geqslant 2$.

Let an edge $u_{i} v_{p}-u_{j} v_{p}$ where $i, j \in\left\{1,2, \ldots, n_{1}\right\}$ and $p \in\left\{1,2, \ldots, n_{2}\right\}$, be deleted. There is a path of length two between $u_{i} v_{p}$ and $u_{j} v_{p}$ in $G$ and the distance between any two other vertices is not affected by the removal of this edge. Thus, the diam $(\mathrm{G})$ remains the same. Therefore, $n_{1}=2$.

Let $n_{1}=2$ and $n_{2}>2$.

Suppose that $d\left(v_{w}, v_{z}\right)=\operatorname{diam}\left(H_{2}\right)$. Let an edge $u_{1} v_{z}-u_{2} v_{z}$, be deleted. Then $d\left(u_{1} v_{z}, u_{2} v_{z}\right)=3 \leqslant \operatorname{diam}(G)$ and the distance between $u_{1} v_{w}, u_{2} v_{z}$ is diam $(\mathrm{G})$. Also, the distance between any two other vertices is not affected by the removal of this edge. Thus, the diam $(\mathrm{G})$ remains the same. Hence, for a connected graph $H_{2}$ with $n_{2}>2$ vertices there exist some $e \in E(G)$ such that $\operatorname{diam}(G-e)<\operatorname{diam}(G)$. Therefore, $n_{2}=2$.

Hence, $H_{1}=H_{2}=K_{2}$.

Theorem 2.1.5. Let $G \cong H_{1} \square H_{2}$.
(a) If both $H_{1}$ and $H_{2}$ are complete graphs with $n_{1}, n_{2}>2$, then $D^{1}(G)=2$.
(b) If $H_{1}$ is a complete graph and $H_{2}$ is a not complete graph, then $D^{1}(G) \leqslant \delta\left(H_{2}\right)$.
(c) If both $H_{1}$ and $H_{2}$ are not complete graphs, then $D^{1}(G) \leqslant \Delta(G)-1$.

Proof. Let $u_{x}, u_{y}$ be a pair of diametral vertices in $H_{1}$, by a path $u_{x}-u_{x+1}-u_{x+2}-\ldots-u_{y-1}-u_{y}$ and $v_{w}, v_{z}$ be a pair of diametral vertices in $H_{2}$, by a path $v_{w}-v_{w+1}-v_{w+2}-\ldots-$ $v_{z-1}-v_{z}$.
(a) $H_{1}$ and $H_{2}$ are complete graphs with $n_{1}, n_{2}>2$.

Let the two edges $u_{i} v_{p}-u_{j} v_{p}$ and $u_{i} v_{q}-u_{j} v_{q}$ where $i \neq j \in\left\{1,2, \ldots, n_{1}\right\}$ and $p \neq q \in\left\{1,2, \ldots, n_{2}\right\}$, be deleted. Then $d\left(u_{i} v_{p}, u_{j} v_{q}\right)=3$ by a path $u_{i} v_{p}-u_{i} v_{q}-u_{x} v_{q}-u_{j} v_{q}$. Hence, $D^{1}(G)=2$.
(b) $H_{1}$ is a complete graph and $H_{2}$ is a not complete graph.

Let $d\left(v_{w}, v_{z}\right)=\operatorname{diam}\left(H_{2}\right)$. Consider a pair of vertices $u_{i} v_{w}$, $u_{i} v_{z}$ in $G$. Let the $\delta\left(H_{2}\right)$ edges $u_{i} v_{q}-u_{i} v_{r}$, where $v_{r}$ S are the neighbours of $v_{q}$ and $r \in\left\{1,2, \ldots, n_{2}\right\}$, be deleted. Then, the $\operatorname{diam}(\mathrm{G})$ increases by a path $u_{i} v_{w}-u_{j} v_{w}-u_{j} v_{w+1}-u_{j} v_{w+2} \ldots u_{j} v_{z}-$ $u_{i} v_{z}$ where $d\left(u_{i} v_{w}, u_{j} v_{w}\right)=1, d\left(u_{i} v_{z}, u_{j} v_{z}\right)=1$ and $d\left(u_{j} v_{w}, u_{j} v_{z}\right)$ $=\operatorname{diam}\left(H_{2}\right)$. Also, the distance between any two other vertices
is not affected by the removal of these edges.
Hence, $D^{1}(G) \leqslant \delta\left(H_{2}\right)$, since $\operatorname{deg}\left(v_{q}\right)=\delta\left(H_{2}\right)$.
(c) $H_{1}$ and $H_{2}$ are not complete graphs.

Consider a pair of diametral vertices $u_{x} v_{w}, u_{y} v_{z}$ in $G$. Let the edges $u_{y} v_{z-1}-u_{i} v_{q}$ where $i \in\left\{1,2, \ldots, n_{1}\right\}, v_{z-1}$ is a neighbour of $v_{z}$ in $H_{2}$ and $q \neq z \in\left\{1,2, \ldots, n_{2}\right\}$, be deleted. Then the $\operatorname{diam}(\mathrm{G})$ increases by a path $u_{x} v_{w}-u_{x+1} v_{w}-\ldots-u_{y} v_{w}-$ $u_{y} v_{w+1}-\ldots-u_{y} v_{z}-u_{y} v_{z-1}$ where $d\left(u_{x} v_{w}, u_{x} v_{z}\right)=\operatorname{diam}\left(H_{2}\right)$ and $d\left(u_{x} v_{z}, u_{y} v_{z-1}\right)=\operatorname{diam}\left(H_{1}\right)-1$.

Hence, $D^{1}(G) \leqslant \Delta(G)-1$, since $\operatorname{deg}\left(u_{y} v_{z-1}\right) \leqslant \Delta(G)$.

Theorem 2.1.6. Let $G \cong H_{1} \square H_{2}$. Then $D^{-1}(G)=1$ if and only if $G$ is any one of the following graphs where, (a) $H_{1}$ is a complete graph and $H_{2}$ is a not complete graph with $D^{-2}\left(H_{2}\right)=1$.
(b) $H_{1}$ is a not complete graph with a universal vertex or there exist a vertex in $H_{1}$ that is on at least one path between any two diametral vertices and $H_{2}$ is a not complete graph with $D^{-1}\left(H_{2}\right)=1$.

Proof. Let $u_{x}, u_{y}$ be a pair of diametral vertices in $H_{1}$, by
a path $u_{x}-u_{x+1}-u_{x+2}-\ldots-u_{y-1}-u_{y}$ and $v_{w}, v_{z}$ be a pair of diametral vertices in $H_{2}$, by a path $v_{w}-v_{w+1}-v_{w+2}-\ldots-$ $v_{z-1}-v_{z}$.
(a) Let $H_{1}$ be a complete graph and $H_{2}$ be a not complete graph with $D^{-2}\left(H_{2}\right)=1$ and the addition of an edge $v_{p}-v_{q}$ in $H_{2}$ decreases the diam $\left(H_{2}\right)$ by two. Now, the addition of an edge $u_{1} v_{p}-u_{1} v_{q}$ in $G$ decreases the diam(G).
(b) Let $H_{2}$ be a not complete graph with $D^{-1}\left(H_{2}\right)=1$ and $H_{1}$ has a universal vertex $u_{i}$ or there exist a vertex $u_{j}$ in $H_{1}$ that is on at least one path between any two diametral vertices. Now, the addition of an edge $u_{i} v_{p}-u_{i} v_{q}$ or $u_{j} v_{p}-u_{j} v_{q}$ in $G$ decreases the diam $(G)$.

Conversely suppose that $D^{-1}(G)=1$. If both $H_{1}$ and $H_{2}$ are complete graphs, then $\operatorname{diam}(\mathrm{G})=2$ and the addition of an edge in $G$ will not decrease the $\operatorname{diam}(\mathrm{G})$.

Suppose that $H_{1}$ is a complete graph.
Consider a pair of diametral vertices $u_{x} v_{w}, u_{y} v_{z}$ in $G$ and $u_{x} v_{w}-$ $u_{i} v_{w}-u_{i} v_{w+1}-\ldots-u_{i} v_{z}-u_{y} v_{z}$ is a path between them. Let an edge $u_{i} v_{p}-u_{i} v_{q}$, be added in $G$. Then, $d\left(u_{x} v_{w}, u_{i} v_{w}\right)=1$ and
$d\left(u_{i} v_{z}, u_{y} v_{z}\right)=1$, since $H_{1}$ is a complete graph. Now, consider the distance between the remaining vertices in the diametral path, then the $\operatorname{diam}(\mathrm{G})$ decreases by one, only if $d\left(u_{i} v_{w}, u_{i} v_{z}\right)$ $=\operatorname{diam}\left(H_{2}\right)-2$. Hence, to decrease the $\operatorname{diam}(\mathrm{G})$ by one, the distance between $u_{i} v_{w}$ and $u_{i} v_{z}$ should be decreased by two, by the addition of a single edge. Thus, $H_{2}$ is a not complete graph with $D^{-2}\left(H_{2}\right)=1$.

Suppose that $D^{-1}\left(H_{2}\right)=1$.
Consider a pair of diametral vertices $u_{x} v_{w}, u_{y} v_{z}$ in $G$. Let an edge $u_{i} v_{p}-u_{i} v_{q}$, be added in $G$. If $u_{i}$ is not a universal vertex of $H_{1}$, then a diametral path between them does not contain the edge $u_{i} v_{p}-u_{i} v_{q}$. Thus, the diam(G) remains the same. Hence, $H_{1}$ is a not complete graph with a universal vertex.

Let $u_{x}, u_{y}$ and $u_{s}, u_{t}$ be the pairs of diametral vertices of $H_{1}$ where $u_{i}$ is a vertex in a diametral path between $u_{x}, u_{y}$ and $u_{i}$ is a vertex not in any of the diametral path between $u_{s}, u_{t}$ in $H_{1}$. Consider the pairs of diametral vertices $u_{x} v_{w}$, $u_{y} v_{z}$ and $u_{s} v_{w}, u_{t} v_{z}$ in $G$. Let an edge $u_{i} v_{p}-u_{i} v_{q}$, be added in $G$. Then, $d\left(u_{x} v_{w}, u_{y} v_{z}\right)=\operatorname{diam}(\mathrm{G})-1$, by a path $u_{x} v_{w}-$ $u_{x+1} v_{w}-\ldots-u_{i} v_{w}-u_{i} v_{w+1}-\ldots-u_{i} v_{z}-\ldots-u_{y} v_{z}$. Also,
$d\left(u_{s} v_{w}, u_{t} v_{z}\right)=\operatorname{diam}(G)$, since $u_{i}$ is not in any of the diametral path between $u_{s}$ and $u_{t}$ in $H_{1}$. Thus, the diam $(\mathrm{G})$ remains the same. Hence, $H_{1}$ is a not complete graph with a universal vertex or there exist a vertex in $H_{1}$ that is on at least one path between any two diametral vertices.

Corollary 2.1.7. There does not exist a graph $G \cong H_{1} \square H_{2}$ such that $G$ is diameter maximal.

Proof. In Theorem 2.1.6 we have characterized the Cartesian product of graphs whose diameter decreases by the addition of a single edge. Hence, we need to prove the theorem only for such Gs.

Let $d\left(u_{x}, u_{y}\right)=\operatorname{diam}\left(H_{1}\right)$ and $d\left(v_{w}, v_{z}\right)=\operatorname{diam}\left(H_{2}\right)$. Consider a pair of diametral vertices $u_{x} v_{w}, u_{y} v_{z}$ in $G$. Let an edge $u_{x} v_{w+1}-u_{x+1} v_{w}$ where $u_{x+1}$ is a neighbour of $u_{x}$ in $H_{1}$ and $v_{w+1}$ is a neighbour of $v_{w}$ in $H_{2}$, be added in $G$. Then the added edge does not decrease the distance between them in $G$. Thus, $d\left(u_{x} v_{p}, u_{y} v_{q}\right)=\operatorname{diam}(G)$. Hence, there exist $e \notin E(G)$ such that $\operatorname{diam}(G+e)=\operatorname{diam}(G)$.

### 2.2 Diameter variability of the strong product of graphs

If both $H_{1}$ and $H_{2}$ are complete graphs, then $G \cong H_{1} \boxtimes H_{2}$ is a complete graph and the deletion of any edge increases the diam(G).

Theorem 2.2.1. Let $G \cong H_{1} \boxtimes H_{2}$. Then $D^{0}(G) \geqslant 6$.

Proof. Let $G \cong H_{1} \boxtimes H_{2}$.
Then $\operatorname{diam}(\mathrm{G})=\max \left\{\operatorname{diam}\left(H_{1}\right), \operatorname{diam}\left(H_{2}\right)\right\}$.

We shall prove the theorem by showing that there exist at least six edges in $G$ that can be deleted without altering the diam $(G)$ by considering the following cases.

Let $u_{x}, u_{y}$ be a pair of diametral vertices in $H_{1}$, by a path $u_{x}-u_{x+1}-u_{x+2}-\ldots-u_{y-1}-u_{y}$.

Case 1: $H_{1}$ is a not complete graph and $H_{2}$ is any connected graph with $n_{2} \geqslant 4$ and $\operatorname{diam}\left(H_{2}\right)<\operatorname{diam}\left(H_{1}\right)$.

We shall prove that $D^{0}(G) \geqslant n_{1} m_{2}$.
Let $d\left(v_{w}, v_{z}\right)=L$ in $H_{2}$ by a path $v_{w}-v_{w+1}-v_{w+2}-\ldots-$
$v_{z-1}-v_{z}$. Consider a pair of diametral vertices $u_{x} v_{w}, u_{y} v_{z}$ in $G$. Let the edges $u_{i} v_{p}-u_{i} v_{q}$ where $i \in\left\{1,2, \ldots, n_{1}\right\}$ and $p, q \in\left\{1,2, \ldots, n_{2}\right\}$, be deleted. There are paths $u_{i} v_{p}-u_{i+1} v_{p+1}-$ $u_{i} v_{p+2}-\ldots-u_{i} v_{q-1}-u_{i+1} v_{q}-u_{i} v_{q}$ or $u_{i} v_{p}-u_{i+1} v_{p+1}-u_{i} v_{p+2}-$ $\ldots-u_{i+1} v_{q-1}-u_{i} v_{q}$ of length $\operatorname{diam}\left(H_{2}\right)+1$ or $\operatorname{diam}\left(H_{2}\right)$ between $u_{i} v_{p}$ and $u_{j} v_{p}$ when $\operatorname{diam}\left(H_{2}\right)$ is odd or even respectively, where $u_{i+1}$ is a neighbour of $u_{i}$ in $H_{1}$. Also, $d\left(u_{x} v_{w}, u_{y} v_{z}\right)=\operatorname{diam}(G)$ by a path $u_{x} v_{w}-u_{x+1} v_{w}-u_{x+2} v_{w}-\ldots-u_{i} v_{w}-\ldots-$ $u_{y-2} v_{z-2}-u_{y-1} v_{z-1}-u_{y} v_{z}$ where $d\left(u_{x} v_{w}, u_{i} v_{w}\right)=\operatorname{diam}\left(H_{1}\right)-L$, and $d\left(u_{i} v_{w}, u_{y} v_{z}\right)=L$. Thus, the diam $(\mathrm{G})$ remains the same.

Now, we consider $n_{2}=2,3$.
(a) $G \cong P_{3} \boxtimes K_{2}$.

Let the bold edges in Fig 2.2 be deleted. Then it is clear that $D^{0}(G)=6$.

Fig 2.2: $P_{3} \boxtimes K_{2}$.
(b) $H_{1}$ is a not complete graph with $n_{1} \geqslant 4$ and $H_{2}=K_{2}$.

Consider the three vertices $u_{p}, u_{q}$ and $u_{r}$ in $H_{1}$ which form a path $P_{3}$. Now, $P_{3} \boxtimes K_{2}$ is a subgraph of $G$. Let the six bold edges as in Fig 2.2 and an edge $u_{1} v_{s}-u_{2} v_{s}$, be deleted. There is a path of length two between these pairs of vertices and the distance between any two other vertices is not affected by the removal of these edges. Thus, $D^{0}(G)>6$.
(c) $G \cong P_{3} \boxtimes K_{3}, P_{4} \boxtimes P_{3}$ and $P_{4} \boxtimes K_{3}$.

Fig 2.3: (i) $P_{3} \boxtimes K_{3}$ (ii) $P_{4} \boxtimes P_{3}$ (iii) $P_{4} \boxtimes K_{3}$.

From Fig 2.3 it is clear that $D^{0}(G)>6$.
(d) $H_{1}$ is a not complete graph with $n_{1} \geqslant 4$ and $n_{2}=3$.

Let the edges $u_{i} v_{1}-u_{j} v_{1}$ and $u_{i} v_{3}-u_{j} v_{3}$ where $i, j \in\left\{1, \ldots, n_{1}\right\}$, be deleted. There is a path of length three between these pairs of vertices. Also, $d\left(u_{x} v_{1}, u_{y} v_{1}\right) \leqslant \operatorname{diam}\left(H_{1}\right)$ by a path $u_{x} v_{1}-$ $u_{x+1} v_{2}-\ldots-u_{y-1} v_{2}-u_{y} v_{1}$. Also, $d\left(u_{i} v_{3}, u_{j} v_{3}\right) \leqslant \operatorname{diam}\left(H_{1}\right)$.

Thus, $D^{0}(G)>6$.

Case 2: $H_{1}$ and $H_{2}$ are connected not complete graphs with $n_{1}, n_{2} \geqslant 4$ and $\operatorname{diam}\left(H_{1}\right)=\operatorname{diam}\left(H_{2}\right)$.

Let $G \cong P_{4} \boxtimes P_{4}$. Then clearly $D^{0}(G)>6$.
Consider $G \cong H_{1} \boxtimes H_{2}$. We shall prove that $D^{0}(G) \geqslant m_{1}+m_{2}$. Suppose that $u_{x}, u_{y}$ and $v_{w}, v_{z}$ are the pairs of diametral vertices in $H_{1}$ and $H_{2}$ respectively. Let the edges $u_{1} v_{p}-u_{1} v_{q}, u_{i} v_{1}-u_{j} v_{1}$ where $p, q \in\left\{1,2, \ldots, n_{2}\right\}$ and $i, j \in\left\{1,2, \ldots, n_{1}\right\}$, be deleted. Then, $d\left(u_{1} v_{w}, u_{1} v_{z}\right)=\operatorname{diam}\left(H_{2}\right)$ by a path $u_{1} v_{w}-u_{2} v_{w+1}-$ $u_{2} v_{w+2}-\ldots-u_{2} v_{z-1}-u_{1} v_{z}$ and $d\left(u_{x} v_{1}, u_{y} v_{1}\right)=\operatorname{diam}\left(H_{1}\right)$ by a path $u_{x} v_{1}-u_{x+1} v_{2}-u_{x+2} v_{2}-\ldots u_{y-1} v_{2}-u_{y} v_{1}$. Also, the distance between any two other vertices is not affected by the removal of these edges. Thus, the diam $(\mathrm{G})$ remains the same and hence $D^{0}(G)>6$.

Next, we consider $n_{1} \geqslant 3$ and $n_{2}=3$.
(a) $G \cong P_{3} \boxtimes P_{3}$.

Let the bold edges in Fig 2.4 be deleted. Then it is clear that $D^{0}(G)>6$.
(b) $G \cong H_{1} \boxtimes P_{3}$ where $n_{1}=4$.

Fig 2.4: $P_{3} \boxtimes P_{3}$.
By an exhaustive verification of all such graphs, it follows that $D^{0}(G)>6$.
(c) $G \cong H_{1} \boxtimes P_{3}$ where $n_{1} \geqslant 5$.

We shall prove that $D^{0}(G) \geqslant 2 m_{1}$.
Let the edges $u_{p} v_{1}-u_{q} v_{1}$ and $u_{p} v_{3}-u_{q} v_{3}$ where $p, q \in\left\{1,2, \ldots, n_{1}\right\}$, be deleted. Then, $d\left(u_{x} v_{1}, u_{y} v_{1}\right) \leqslant \operatorname{diam}\left(H_{1}\right)$ by a path $u_{x} v_{1}-$ $u_{x+1} v_{2}-\ldots-u_{y-1} v_{2}-u_{y} v_{1}$ and $d\left(u_{x} v_{3}, u_{y} v_{3}\right) \leqslant \operatorname{diam}\left(H_{1}\right)$.

Also, the distance between any two other vertices is not affected by the removal of these edges. Thus, the diam(G) remains the same and hence $D^{0}(G)>6$.

Corollary 2.2.2. $D^{0}(G)=6$ if and only if $H_{1}=P_{3}$ and $H_{2}=K_{2}$.

Corollary 2.2.3. Let $G \cong H_{1} \boxtimes H_{2}$ where $H_{1}$ and $H_{2}$ are connected graphs with $\operatorname{diam}\left(H_{2}\right)<\operatorname{diam}\left(H_{1}\right)$. Then $D^{0}(G) \geqslant n_{1} m_{2}$.

Theorem 2.2.4. Let $G \cong H_{1} \boxtimes H_{2}$. Then $D^{1}(G)=1$ if and only if $G$ is any one of the following graphs where,
(a) both $H_{1}$ and $H_{2}$ are complete graphs.
(b) $H_{1}$ and $H_{2}$ are not complete graphs with $\operatorname{diam}\left(H_{1}\right)=\operatorname{diam}\left(H_{2}\right)$ and either $H_{1}$ or $H_{2}$ have at least one pair of vertices with exactly one diametral path or there exist an edge in $H_{1}$ or $H_{2}$ that is on all diametral paths between any two vertices.

Proof. Let $G \cong K_{n_{1}} \boxtimes K_{n_{2}}$ where $n_{1}, n_{2} \geqslant 2$. Then $G$ is a complete graph and the deletion of any edge increases the diam(G).

Let $H_{1}$ and $H_{2}$ are not complete graphs with $\operatorname{diam}\left(H_{1}\right)=$ $\operatorname{diam}\left(H_{2}\right)$ and either $H_{1}$ or $H_{2}$ have at least one pair of vertices with exactly one diametral path or there exist an edge in $H_{1}$ or $H_{2}$ that is on all diametral paths between any two vertices. Let $u_{x}, u_{y}$ be a pair of diametral vertices in $H_{1}$, by a path $u_{x}-u_{x+1}-u_{x+2}-\ldots-u_{y-1}-u_{y}$ and $v_{w}, v_{z}$ be a pair of diametral vertices in $H_{2}$, by a path $v_{w}-v_{w+1}-v_{w+2}-\ldots-v_{z-1}-v_{z}$. Consider a pair of diametral vertices $u_{x} v_{w}, u_{y} v_{z}$ in $G$, by a path $u_{x} v_{w}-u_{x+1} v_{w+1}-u_{x+2} v_{w+2} \ldots u_{y-1} v_{z-1}-u_{y} v_{z}$. Let an edge $u_{x} v_{w}-u_{x+1} v_{w+1}$, be deleted. Then, $d\left(u_{x} v_{w}, u_{y} v_{z}\right)=\operatorname{diam}(G)+1$
by a path $u_{x} v_{w}-u_{x} v_{w+1}-u_{x+1} v_{w+1} \ldots u_{y-1} v_{z-1}-u_{y} v_{z}$ where $d\left(u_{x} v_{w}, u_{x+1} v_{w+1}\right)=2, d\left(u_{x+1} v_{w+1}, u_{y} v_{z}\right)=\operatorname{diam}(G)-1$.

Conversely suppose that $D^{1}(G)=1$.

Suppose that $H_{1}$ is a not complete graph and $H_{2}$ is a complete graph.

Let an edge $u_{i} v_{p}-u_{i} v_{q}$ or $u_{i} v_{p}-u_{j} v_{p}$ or $u_{i} v_{p}-u_{j} v_{p+1}$, be deleted. Then $d\left(u_{i} v_{p}, u_{i} v_{q}\right)=d\left(u_{i} v_{p}, u_{j} v_{p}\right)=d\left(u_{i} v_{p}, u_{j} v_{p+1}\right)=2$ by the paths $u_{i} v_{p}-u_{i+1} v_{q}-u_{i} v_{q}, u_{i} v_{p}-u_{j} v_{p+1}-u_{j} v_{p}$ and $u_{i} v_{p}-u_{i} v_{p+1}-u_{j} v_{p+1}$ respectively. Also, the distance between any two other vertices is not affected by the removal of this edge. Thus, when one factor is a complete graph and the other factor is a not complete graph, a minimum of two edges should be deleted to increase the diam(G). Hence, both the factors should be complete. This proves (a).

Suppose that $H_{1}$ and $H_{2}$ are not complete graphs with $\operatorname{diam}\left(H_{1}\right)>\operatorname{diam}\left(H_{2}\right)$.

Consider a pair of diametral vertices $u_{x} v_{w}, u_{y} v_{z}$ in $G$ by a path $u_{x} v_{w}-u_{x+1} v_{w+1}-u_{x+2} v_{w+2} \ldots u_{y-1} v_{z-1}-u_{y} v_{z}$. Let an edge $u_{x} v_{w}-u_{x+1} v_{w+1}$, be deleted. Then, $d\left(u_{x} v_{w}, u_{y} v_{z}\right)=\operatorname{diam}\left(H_{2}\right)+1$
by a path $u_{x} v_{w}-u_{x} v_{w+1}-u_{x+1} v_{w+1} \ldots u_{y-1} v_{z-1}-u_{y} v_{z}$ where
$d\left(u_{x} v_{w}, u_{x+1} v_{w+1}\right)=2, d\left(u_{x+1} v_{w+1}, u_{y} v_{z}\right)=\operatorname{diam}\left(H_{2}\right)-1$.
Hence, $\operatorname{diam}(G)$ remains the same. Thus, when $H_{1}$ and $H_{2}$ are not complete graphs with different diameter, at least two edges should be deleted to increase the $\operatorname{diam}(G)$.

Suppose that $H_{1}$ and $H_{2}$ are not complete graphs with $\operatorname{diam}\left(H_{1}\right)=\operatorname{diam}\left(H_{2}\right)$.

Consider a pair of diametral vertices $u_{x} v_{w}, u_{y} v_{z}$ in $G$. Since, $\operatorname{diam}\left(H_{1}\right)=\operatorname{diam}\left(H_{2}\right), u_{x} v_{w}-u_{x+1} v_{w+1}-u_{x+2} v_{w+2} \ldots u_{y-1} v_{z-1}-$ $u_{y} v_{z}$ is a shortest path between them in $G$. Then, the deletion of an edge $u_{i} v_{j}-u_{i+1} v_{j+1}$ from this path increases the $\operatorname{diam}(G)$ only if either there exist only one diametral path between $u_{x}$, $u_{y}$ in $H_{1}$ and $v_{w}, v_{z}$ in $H_{2}$ or $u_{i}-u_{i+1}$ is an edge in $H_{1}$ that is on all diametral paths between any two vertices in $H_{1}$ and $v_{j}-v_{j+1}$ is an edge in $H_{2}$ that is on all diametral paths between any two vertices in $H_{2}$. Otherwise, there exist an alternative path of length $\operatorname{diam}\left(H_{1}\right)$ between $u_{x} v_{w}, u_{y} v_{z}$ in $G$. Hence, $H_{1}$ and $H_{2}$ are not complete graphs with $\operatorname{diam}\left(H_{1}\right)=\operatorname{diam}\left(H_{2}\right)$ and either $H_{1}$ or $H_{2}$ have at least one pair of vertices with exactly one diametral path or there exist an edge in $H_{1}$ or $H_{2}$ that is on all diametral paths between any two vertices. This proves (b).

Corollary 2.2.5. $G \cong H_{1} \boxtimes H_{2}$ is diameter minimal if and only if both $H_{1}$ and $H_{2}$ are complete graphs.

Theorem 2.2.6. Let $G \cong H_{1} \boxtimes H_{2}$.
Then $D^{1}(G) \leqslant \alpha\left(1+\delta\left(H_{2}\right)\right)$ where $\alpha$ is the minimum number of edge disjoint paths of length diam $\left(H_{1}\right)$ between any two vertices in $H_{1}$.

Proof. Let $u_{x}$ and $u_{y}$ be a pair of diametral vertices in $H_{1}$, by a path $u_{x}-u_{x+1}-u_{x+2}-\ldots-u_{y-1}-u_{y}$. Consider a pair of diametral vertices $u_{x} v_{z}$ and $u_{y} v_{z}$ in $G$. Let the edges $u_{x} v_{z}-u_{q} v_{z}, u_{x} v_{z}-$ $u_{q} v_{r}$ where $u_{q} \mathrm{~S}$ are the vertices adjacent to $u_{x}$ in $H_{1}$ and $v_{r} \mathrm{~S}$ are the vertices adjacent to $v_{z}$ in $H_{2}$, be deleted. Then, $d\left(u_{x} v_{z}, u_{y} v_{z}\right)$ $=\operatorname{diam}(G)+1$ by a path $u_{x} v_{z}-u_{x} v_{z+1}-u_{x+1} v_{z}-\ldots-u_{y-1} v_{z}-$ $u_{y} v_{z}$ where $d\left(u_{x+1} v_{z}, u_{y} v_{z}\right)=\operatorname{diam}(G)-1, d\left(u_{x} v_{z}, u_{x+1} v_{z}\right)=2$. Also, $d\left(u_{x} v_{z}, u_{q} v_{z}\right)=2$ and $d\left(u_{x} v_{z}, u_{q} v_{r}\right)=2$, since there are paths of length two between them.

Thus, $D^{1}(G) \leqslant \alpha\left(1+\delta\left(H_{2}\right)\right)$.

Theorem 2.2.7. Let $G \cong H_{1} \boxtimes H_{2}$ be connected graph. Then $D^{-1}(G)=1$ if and only if $H_{2}$ has a universal vertex and $H_{1}$ is a
connected graph with diam $\left(H_{1}\right) \geqslant 4$ and $D^{-2}\left(H_{1}\right)=1$ when an edge is added between a diametral vertex and any other vertex of $H_{1}$ and $D^{-1}\left(H_{1}\right)=1$ when an edge is added between any two other vertices of $H_{1}$.

Proof. Let $G \cong H_{1} \boxtimes H_{2}$ and $\operatorname{diam}(G)=\operatorname{diam}\left(H_{1}\right)$.

Let $u_{x}, u_{y}$ be a pair of diametral vertices in $H_{1}$, by a path $u_{x}-u_{x+1}-u_{x+2}-\ldots-u_{y-1}-u_{y}$ and $v_{w}, v_{z}$ be a pair of diametral vertices in $H_{2}$, by a path $v_{w}-v_{w+1}-v_{w+2}-\ldots-v_{z-1}-v_{z}$. Suppose that $v_{1}$ is a universal vertex of $H_{2}$.

Let $D^{-1}\left(H_{1}\right)=1$ where $\operatorname{diam}\left(H_{1}\right) \geqslant 4$.

Consider a pair of diametral vertices $u_{x} v_{w}, u_{y} v_{z}$ in $G$. Let an edge $u_{p} v_{1}-u_{q} v_{1}$ where $u_{p} \neq u_{x}, u_{q} \neq u_{y}$, be added in $G$. Then, $d\left(u_{x} v_{w}, u_{y} v_{z}\right)=\operatorname{diam}(G)-1$ by a path $u_{x} v_{w}-$ $u_{x+1} v_{1}-u_{x+2} v_{1} \ldots u_{y-1} v_{1}-u_{y} v_{z}$ where $d\left(u_{x} v_{w}, u_{x+1} v_{1}\right)=1$, $d\left(u_{x+1} v_{1}, u_{y-1} v_{1}\right)=\operatorname{diam}(G)-3$ and $d\left(u_{y-1} v_{1}, u_{y} v_{z}\right)=1$.

Consider a pair of diametral vertices $u_{x} v_{w}, u_{y} v_{z}$ in $G$. Let an edge $u_{x} v_{1}-u_{y} v_{1}$, be added in $G$. Then, $d\left(u_{x} v_{w}, u_{y} v_{z}\right)=3$ by a path $u_{x} v_{w}-u_{x} v_{1}-u_{y} v_{1}-u_{y} v_{z}$.

Suppose that $D^{-2}\left(H_{1}\right)=1$ where $\operatorname{diam}\left(H_{1}\right) \geqslant 4$.

Consider a pair of diametral vertices $u_{x} v_{w}, u_{y} v_{z}$ in $G$. Let an edge $u_{x} v_{1}-u_{i} v_{1}$ where $u_{i}$ is a vertex in a diamertal path between $u_{x}$ and $u_{y}$ in $H_{1}$, be added in $G$. Then, $d\left(u_{x} v_{w}, u_{y} v_{z}\right)=\operatorname{diam}(G)-1$ by a path $u_{x} v_{w}-u_{x} v_{1}-u_{i} v_{1}-\ldots-u_{y-1} v_{1}-u_{y} v_{z}$ where $d\left(u_{x} v_{w}, u_{x} v_{1}\right)=1, d\left(u_{x} v_{1}, u_{y-1} v_{1}\right)=\operatorname{diam}(G)-3$ and $d\left(u_{y-1} v_{1}, u_{y} v_{z}\right)=1$. Thus, the distance between any two vertices in $G$ is at most $\operatorname{diam}(\mathrm{G})-1$.

Conversely suppose that $D^{-1}(G)=1$. If both $H_{1}$ and $H_{2}$ are complete graphs, then $G$ is a complete graph. If $\operatorname{diam}\left(H_{1}\right)=2$, then the addition of a single edge in $G$ will not make $G$ a complete graph. Also, if $\operatorname{diam}\left(H_{1}\right)=3$, then the addition of a single edge in $G$ will not decrease the $\operatorname{diam}(G)$, since there exist a path of length at least three between any pair of diametral vertices in $G$. Thus, it is clear that $H_{1}$ is a connected graph with $\operatorname{diam}\left(H_{1}\right) \geqslant 4$.

Suppose that $H_{1}$ is any connected graph and $H_{2}$ is any connected graph without a universal vertex.

Let $v_{p}$ and $v_{q}$ be a pair of non adjacent vertices in $H_{2}$. Con-
sider a pair of diametral vertices $u_{x} v_{q}, u_{y} v_{q}$ in $G$. Let an edge $u_{i} v_{p}-u_{j} v_{p}$, be added in $G$. Since $v_{p}$ is not adjacent to $v_{q}$, the diametral path between $u_{x} v_{q}$ and $u_{y} v_{q}$ does not contain the edge $u_{i} v_{p}-u_{j} v_{p}$ in $G$. Hence, to decrease the diam(G), $H_{2}$ should contain a universal vertex.

Suppose that $H_{2}$ has a universal vertex $v_{1}$. Consider a pair of diametral vertices $u_{x} v_{w}, u_{y} v_{w}$ in $G$. Let an edge $u_{i} v_{1}-u_{j} v_{1}$, be added in $G$.

Let $i \neq x, j \neq y$.
Consider a diametral path $u_{x} v_{w}-u_{x+1} v_{1}-u_{x+2} v_{1}-\ldots-u_{y-1} v_{1}-$ $u_{y} v_{w}$ between $u_{x} v_{w}, u_{y} v_{w}$ in $G$. Then $d\left(u_{x} v_{w}, u_{x+1} v_{1}\right)=1$ and $d\left(u_{y-1} v_{1}, u_{y} v_{w}\right)=1$, since $H_{2}$ has a universal vertex. Now, consider the distance between the remaining vertices in the diametral path. Then, the diam(G) decreases by one only if $d\left(u_{x+2} v_{1}, u_{y-1} v_{1}\right)=\left[\operatorname{diam}\left(H_{1}\right)-2\right]-1=\operatorname{diam}\left(H_{1}\right)-3$. Hence, to decrease the $\operatorname{diam}(\mathrm{G})$ by one, the distance between $u_{x} v_{1}$ and $u_{y} v_{1}$ should be decreased by one, by the addition of a single edge.

Let $i=x, j=y$.
Then, $d\left(u_{x} v_{w}, u_{y} v_{w}\right)=3$ by a path $u_{x} v_{w}-u_{x} v_{1}-u_{y} v_{1}-u_{y} v_{w}$, since $H_{2}$ has a universal vertex. From the previous case it follows
that $\operatorname{diam}(\mathrm{G})$ decreases, only if $d\left(u_{p} v_{1}, u_{q} v_{1}\right) \leqslant \operatorname{diam}\left(H_{1}\right)-1$. Hence, to decrease the $\operatorname{diam}(\mathrm{G})$ by one, the distance between $u_{x} v_{1}$ and $u_{y} v_{1}$ should be decreased by one, by the addition of a single edge.

Now, let $i=x, j \neq y$.
Consider a diametral path $u_{x} v_{w}-u_{x} v_{1}-u_{x+1} v_{1}-\ldots-u_{y-1} v_{1}-$ $u_{y} v_{w}$ between $u_{x} v_{w}, u_{y} v_{w}$ in $G$. Then $d\left(u_{x} v_{w}, u_{x} v_{1}\right)=1$ and $d\left(u_{y-1} v_{1}, u_{y} v_{w}\right)=1$, since $H_{2}$ has a universal vertex. Now, consider the distance between the remaining vertices in the diametral path. Then, the $\operatorname{diam}(G)$ decreases by one, only if $d\left(u_{x} v_{1}, u_{y-1} v_{1}\right)=\left[\operatorname{diam}\left(H_{1}\right)-1\right]-2=\operatorname{diam}\left(H_{1}\right)-3$. Hence, to decrease the $\operatorname{diam}(\mathrm{G})$ by one, the distance between $u_{x} v_{1}$ and $u_{y-1} v_{1}$ should be decreased by two, by the addition of a single edge.

Corollary 2.2.8. There does not exist a graph $G \cong H_{1} \boxtimes H_{2}$ such that $G$ is diameter maximal.

Proof. In Theorem 2.2.7 we have characterized the strong product of graphs whose diameter decreases by the addition of a single edge. Hence, we need to prove the theorem only for such $G$ s.
2.3. Diameter variability of the lexicographic product of graphs

Suppose that $H_{2}$ is a not complete graph with a universal vertex and $H_{1}$ is a connected graph with $D^{-1}\left(H_{1}\right)=1$ or $D^{-2}\left(H_{1}\right)=1$ with $\operatorname{diam}\left(H_{1}\right) \geqslant 4$. Let an edge $u_{x} v_{p}-u_{x} v_{q}$ be added in $G$, then the $\operatorname{diam}(G)$ remains the same, since $\operatorname{diam}(G)=\operatorname{diam}\left(H_{1}\right)$.

Suppose that $H_{2}$ is a complete graph and $H_{1}$ is a connected graph with $D^{-1}\left(H_{1}\right)=1$ or $D^{-2}\left(H_{1}\right)=1$ with $\operatorname{diam}\left(H_{1}\right) \geqslant 4$. Let the three vertices $u_{x}, u_{s}$ and $u_{r}$ form a $P_{3}$ in $H_{1}$. Consider a pair of diametral vertices $u_{x} v_{p}, u_{y} v_{p}$ in $G$. Let an edge $u_{x} v_{q}-u_{r} v_{p}$ where $v_{q}$ is a neighbour of $v_{p}$ in $H_{2}$, be added. Then the addition of an edge $u_{x} v_{q}-u_{r} v_{p}$ does not decrease the distance between them in $G$. Thus, $d\left(u_{x} v_{p}, u_{y} v_{p}\right)=\operatorname{diam}(G)$. Hence, there exist some $e \notin E(G)$ such that $\operatorname{diam}(G+e)=\operatorname{diam}(G)$.

### 2.3 Diameter variability of the lexicographic product of graphs

If both $H_{1}$ and $H_{2}$ are complete graphs, then $G \cong H_{1} \circ H_{2}$ is a complete graph and the deletion of any edge increases the
diam(G).
Theorem 2.3.1. Let $G \cong H_{1} \circ H_{2}$. Then $D^{0}(G) \geqslant 3$.

Proof. Let $G \cong H_{1} \circ H_{2}$. Then $\operatorname{diam}(G)=\operatorname{diam}\left(H_{1}\right)$.
We prove the theorem by showing that there exist at least three edges in $G$ that can be deleted without altering the $\operatorname{diam}(\mathrm{G})$ by considering the following cases.

Let $u_{x}, u_{y}$ be a pair of diametral vertices in $H_{1}$, by a path $u_{x}-u_{x+1}-u_{x+2}-\ldots-u_{y-1}-u_{y}$ and $v_{w}, v_{z}$ be a pair of diametral vertices in $H_{2}$, by a path $v_{w}-v_{w+1}-v_{w+2}-\ldots-v_{z-1}-v_{z}$.

Case 1: $H_{1}$ is a complete graph and $H_{2}$ is a not complete graph or a disconnected graph with $m_{2} \geqslant 1$.
(a) Let $m_{2} \geqslant 2$.

We shall prove that $D^{0}(G) \geqslant n_{1} m_{2}$.
Suppose that $G \cong K_{n_{1}} \circ H_{2}$, then $\operatorname{diam}(\mathrm{G})=2$. Let the edges $u_{i} v_{p}-u_{i} v_{q}$ where $i \in\left\{1,2, \ldots, n_{1}\right\}$ and $p, q \in\left\{1,2, \ldots, n_{2}\right\}$, be deleted. There are paths $u_{i} v_{p}-u_{i+1} v_{p}-u_{i} v_{q}$ of length two between each pair of vertices in $G$. Also, the distance between any two other vertices is not affected by the removal of these edges. Thus, $D^{0}(G) \geqslant n_{1} m_{2} \geqslant 4$.
2.3. Diameter variability of the lexicographic product of graphs
(b) Let $m_{2}=1$.

Suppose that $n_{1}=2$ and $n_{2}=3$.
Let the bold edges in Fig 2.6 be deleted. Then it is clear that $D^{0}(G)=3$.

Suppose that $n_{1}=2$ and $n_{2} \geqslant 4$.
Let the edges $u_{i} v_{p}-u_{j} v_{q}, u_{i} v_{q}-u_{j} v_{q}, u_{i} v_{q}-u_{j} v_{r}$ and $u_{i} v_{r}-u_{j} v_{q}$ where $v_{q}$ is adjacent to $v_{p}$ in $H_{2}$, be deleted. There are paths $u_{i} v_{p}-u_{j} v_{p}-u_{j} v_{q}, u_{i} v_{q}-u_{j} v_{p}-u_{j} v_{q}, u_{i} v_{q}-u_{i} v_{p}-u_{j} v_{r}$ and $u_{i} v_{r}-u_{j} v_{p}-u_{j} v_{q}$ of length two between each pair of vertices.

Also, the distance between any two other vertices is not affected by the removal of these edges. Thus, $D^{0}(G) \geqslant 4$.

Suppose that $n_{1}=3$ and $n_{2}=3$.
Let the bold edges in Fig 2.5 be deleted, then it is clear that $D^{0}(G)>3$.

Fig 2.5: $G: D^{0}(G)>3$.

Suppose that $n_{1}>3$ and $n_{2} \geqslant 3$.
Let the edges $u_{i} v_{1}-u_{j} v_{1}$ where $i, j \in\left\{1,2, \ldots, n_{1}\right\}$, be deleted. There are paths $u_{i} v_{1}-u_{i} v_{2}-u_{j} v_{1}$ of length two between these pairs of vertices in $G$. Also, the distance between any two other vertices is not affected by the removal of these edges.

Thus, $D^{0}(G) \geqslant 4$.

Case 2: $H_{1}$ is a complete graph and $H_{2}$ is a totally disconnected graph.
(a) Let $n_{1}=2$.

Then $G$ has diameter two and the deletion of any edge increases the diam $(\mathrm{G})$.
(b) Let $n_{1} \geqslant 3$.

Let the edges $u_{i} v_{1}-u_{j} v_{1}, u_{i} v_{1}-u_{j} v_{2}, u_{i} v_{2}-u_{j} v_{2}$ and $u_{i} v_{2}-u_{j} v_{1}$, be deleted. There are paths $u_{i} v_{1}-u_{x} v_{1}-u_{j} v_{1}, u_{i} v_{1}-u_{x} v_{2}-u_{j} v_{2}$, $u_{i} v_{2}-u_{x} v_{2}-u_{j} v_{2}$ and $u_{i} v_{2}-u_{x} v_{1}-u_{j} v_{1}$ of length two between each pair of vertices. Also, the distance between any two other vertices is not affected by the removal of these edges.

Thus, $D^{0}(G) \geqslant 4$.

Case 3 : $H_{1}$ is a not complete graph and $H_{2}$ is a not
2.3. Diameter variability of the lexicographic product of graphs
complete graph or a disconnected graph with $m_{2} \geqslant 1$.
(a) Let $n_{1} \geqslant 4$.

We shall prove that $D^{0}(G) \geqslant n_{1} m_{2}$.
Let the edges $u_{i} v_{p}-u_{i} v_{q}$ where $i \in\left\{1,2, \ldots, n_{1}\right\}$ and $p, q \in\left\{1,2, \ldots, n_{2}\right\}$, be deleted. There are paths of length two between these pairs of vertices. Also, the distance between any two other vertices is not affected by the removal of these edges. Thus, $D^{0}(G) \geqslant n_{1} m_{2} \geqslant 4$.
(b) Let $n_{1}=3$.

Let the edges $u_{1} v_{i}-u_{1} v_{j}, u_{1} v_{j}-u_{2} v_{j}, u_{2} v_{j}-u_{3} v_{j}$ and $u_{3} v_{i}-u_{3} v_{j}$ where $u_{2}$ is adjacent to $u_{1}$ and $u_{3}$ in $H_{1}$, be deleted. There are paths of length two between these pairs of vertices. Also, the distance between any two other vertices is not affected by the removal of these edges. Thus, $D^{0}(G) \geqslant 4$.

Case 4 : $H_{1}$ is a not complete graph and $H_{2}$ is a totally disconnected graph.
(a) $H_{1}$ is a not complete graph with diameter two in which no two adjacent vertices of $H_{1}$ have a path of length two between them.

Then, $\operatorname{diam}(G)=2$ and the deletion of an edge increases the diam(G).
(b) $H_{1}$ is a not complete graph with diameter two in which there exist at least one pair of adjacent vertices with a path of length two between them.

Let the edges $u_{i} v_{1}-u_{j} v_{1}, u_{i} v_{1}-u_{j} v_{2}, u_{i} v_{2}-u_{j} v_{2}$ and $u_{i} v_{2}-u_{j} v_{1}$ where there is a path of length two between $u_{1}$ and $u_{2}$ in $H_{1}$, be deleted. There are paths $u_{i} v_{1}-u_{x} v_{1}-u_{j} v_{1}, u_{i} v_{1}-u_{x} v_{2}-u_{j} v_{2}$, $u_{i} v_{2}-u_{x} v_{2}-u_{j} v_{2}$ and $u_{i} v_{2}-u_{x} v_{1}-u_{j} v_{1}$ of length two between each pair of vertices. Also, the distance between any two other vertices is not affected by the removal of these edges.

Thus, $D^{0}(G) \geqslant 4$.
(c) $H_{1}=P_{4}$ and $n_{2}=2$.

Let the bold edges in Fig 2.6 be deleted. Then it is clear that $D^{0}(G)=3$.
(d) $H_{1}=P_{4}$ and $n_{2}>2$.

Let the edges $u_{i} v_{1}-u_{j} v_{1}$ and $u_{i} v_{2}-u_{j} v_{2}$ where $i, j \in\{1,2,3,4\}$, be deleted. There are paths of length at most three between these pair of vertices. Also, the distance between any two other vertices is not affected by the removal of these edges.
2.3. Diameter variability of the lexicographic product of graphs

Thus, $D^{0}(G)>4$.
(e) Let $\operatorname{diam}\left(H_{1}\right) \geqslant 3$.

We shall prove that $D^{0}(G) \geqslant m_{1}$.
Let the edges $u_{i} v_{1}-u_{j} v_{1}$ where $i, j \in\left\{1,2, \ldots, n_{1}\right\}$, be deleted. There are paths of length at most $\operatorname{diam}(G)$ between these pairs of vertices. Also, $d\left(u_{x} v_{1}, u_{y} v_{1}\right)=\operatorname{diam}(G)$ by a path $u_{x} v_{1}-$ $u_{x+1} v_{2}-u_{x+2} v_{2} \ldots u_{y-1} v_{2}-u_{y} v_{1} z$ and the distance between any two other vertices is not affected by the removal of these edges. Thus, $D^{0}(G) \geqslant m_{1} \geqslant 4$.

Hence, $D^{0}(G) \geqslant 3$.

Corollary 2.3.2. $D^{0}(G)=3$ if and only if $G$ is any one of the graphs shown in Fig 2.6.

Fig 2.6: The graphs $G: D^{0}(G)=3$.

Corollary 2.3.3. Let $G \cong H_{1} \circ H_{2}$ where $H_{1}$ and $H_{2}$ are connected graphs. Then $D^{0}(G) \geqslant n_{1} m_{2}$.

Theorem 2.3.4. Let $G \cong K_{n_{1}} \circ H_{2}$ where $n_{1} \geqslant 3$.
Then $D^{0}(G)=n_{2}^{2} m_{1}+n_{1} m_{2}-\left(2 n_{1} n_{2}-3\right)$.

Proof. Consider a spanning tree $T$ of diameter three, of $G$ as shown in Fig 2.7. From $T$, let us construct a spanning subgraph $H$ of $G$ having diameter two as follows.

Consider the vertices $u_{1} v_{p}, u_{x} v_{q}$ where $x \in\left\{2,3, \ldots, n_{1}\right\}$ and $p, q \in\left\{2,3, \ldots, n_{2}\right\}$. Then, $d\left(u_{1} v_{p}, u_{x} v_{q}\right)=3$. Let the edges $u_{2} v_{1}-u_{x} v_{p}$ where $x \in\left\{3,4, \ldots, n_{1}\right\}$ and $p \in\left\{1,2, \ldots, n_{2}\right\}$, be added in $T$. Now, consider the vertices $u_{1} v_{p}, u_{2} v_{q}$ where $p \in\left\{2,3, \ldots, n_{2}\right\}$, then $d\left(u_{1} v_{p}, u_{2} v_{q}\right)=3>2$. Let the edges $u_{3} v_{1}-u_{1} v_{p}$ and $u_{3} v_{1}-u_{2} v_{p}$ where $p \in\left\{2,3, \ldots, n_{2}\right\}$, be added in $T$.

Let the resulting spanning subgraph of $G$ be denoted by $H$. Then $H$ has diameter two.

Hence, $D^{0}(G) \geqslant n_{2}^{2} m_{1}+n_{1} m_{2}-\left(2 n_{1} n_{2}-3\right)$.

Now, to prove the reverse inequality, we proceed as follows. From Corollary 2.3.3 it follows that if the $n_{1} m_{2}$ edges $u_{i} v_{p}-u_{i} v_{q}$ where $i \in\left\{1,2, \ldots n_{1}\right\}$ and $p, q \in\left\{1,2, \ldots n_{2}\right\}$ are deleted, then the diam $(\mathrm{G})$ remains the same. Let the edges $u_{i} v_{p}-u_{j} v_{p}$ where

Fig 2.7: A spanning tree $T$ and the spanning subgraph $H$ of $G$.
$i, j \in\left\{1,2, \ldots n_{1}\right\}$ and $p \in\left\{1,2,3, \ldots n_{2}\right\}$ except $u_{1} v_{1}-u_{r} v_{1}$, $u_{2} v_{1}-u_{r} v_{1}$ where $r \in\left\{2,3, \ldots n_{2}\right\}$, be deleted. There is a path $u_{i} v_{p}-u_{x} v_{1}-u_{j} v_{q}$ of length two between each pair of verices. Now, let the edges $u_{i} v_{p}-u_{j} v_{q}$ where $i, j \in\left\{1,2, \ldots, n_{1}\right\}, p, q \in$ $\left\{1,2, \ldots, n_{2}\right\}$ except $u_{1} v_{1}-u_{i} v_{p}, u_{2} v_{1}-u_{j} v_{p}, u_{3} v_{1}-u_{1} v_{r}$ and $u_{3} v_{1}-$ $u_{2} v_{r}$ where $i \in\left\{2,3, \ldots n_{2}\right\}, j \in\left\{1,3, \ldots n_{2}\right\}, p \in\left\{2,3, \ldots n_{2}\right\}$ and $r \in\left\{2,3, \ldots, n_{2}\right\}$, be deleted. There are paths $u_{i} v_{p}-u_{1} v_{1}-u_{j} v_{q}$, $u_{1} v_{p}-u_{3} v_{1}-u_{2} v_{q}$ of length two between each pair of verices. In both the cases the diam $(\mathrm{G})$ remains the same.

Thus we have a spanning subgraph $H$ with diameter two as shown in Fig 2.7 and the deletion of any edge from $H$ increases the diam $(\mathrm{H})$. So, $D^{0}(G) \leqslant n_{2}^{2} m_{1}+n_{1} m_{2}-\left(2 n_{1} n_{2}-3\right)$.

Hence, $D^{0}(G)=n_{2}^{2} m_{1}+n_{1} m_{2}-\left(2 n_{1} n_{2}-3\right)$.
Theorem 2.3.5. Let $G \cong H_{1} \circ H_{2}$ where $H_{1}$ and $H_{2}$ are connected graphs with $\operatorname{diam}\left(H_{2}\right)<\operatorname{diam}\left(H_{1}\right)$. Then $D^{0}(G) \geqslant n_{2}^{2} m_{1}-\left(m_{1} n_{2}+2 m_{1} m_{2}\right)$.

Proof. Let $u_{x}, u_{y}$ be a pair of diametral vertices in $H_{1}$, by a path $u_{x}-u_{x+1}-u_{x+2}-\ldots-u_{y-1}-u_{y}$.

Suppose that $d\left(v_{p}, v_{q}\right)=L$ in $H_{2}$ by a path $v_{p}-v_{p+1}-v_{p+2}-$ $\ldots-v_{q-1}-v_{q}$. Consider a pair of diametral vertices $u_{x} v_{p}, u_{y} v_{q}$ in $G$. Let the $n_{1} m_{2}$ edges $u_{i} v_{p}-u_{i} v_{q}$ where $i \in\left\{1,2, \ldots n_{1}\right\}$ and $p, q \in\left\{1,2, \ldots n_{2}\right\}$, be deleted. Then from Corollary 2.3.3 it follows that the diam $(\mathrm{G})$ remains the same. Now, let the $n_{2}^{2} m_{1}-\left(m_{1} n_{2}+2 m_{1} m_{2}\right)$ edges $u_{i} v_{p}-u_{j} v_{q}$ where $i, j \in\left\{1,2, \ldots n_{1}\right\}$, $p, q \in\left\{1,2, \ldots n_{2}\right\}, v_{p} \mathrm{~S}$ and $v_{q} \mathrm{~S}$ are not adjacent vertices in $H_{2}$, be deleted. Then, $d\left(u_{x} v_{p}, u_{y} v_{q}\right)=\operatorname{diam}(G)$ by a path $u_{x} v_{p}-$ $u_{x+1} v_{p}-u_{x+2} v_{p}-\ldots-u_{i} v_{p}-u_{i+1} v_{p+1}-\ldots-u_{y-2} v_{q-2}-u_{y-1} v_{q-1}-$ $u_{y} v_{q}$ where $d\left(u_{x} v_{p}, u_{i} v_{q}\right)=\operatorname{diam}\left(H_{1}\right)-L$, and $d\left(u_{i} v_{p}, u_{y} v_{q}\right)=L$. Also, $d\left(u_{i} v_{w}, u_{i} v_{z}\right)=\operatorname{diam}\left(H_{2}\right)$ or $d\left(u_{i} v_{w}, u_{i} v_{z}\right)=\operatorname{diam}\left(H_{2}\right)+1$ when the distance between $v_{w}, v_{z}$ is even or odd respectively. Thus the diam $(\mathrm{G})$ remains the same.

Hence, $D^{0}(G) \geqslant n_{1} m_{2}+n_{2}^{2} m_{1}-\left(n_{1} m_{2}+m_{1} n_{2}+2 m_{1} m_{2}\right)=$
2.3. Diameter variability of the lexicographic product of graphs
$n_{2}^{2} m_{1}-\left(m_{1} n_{2}+2 m_{1} m_{2}\right)$.

Theorem 2.3.6. Let $G \cong H_{1} \circ H_{2}$. Then $D^{1}(G)=1$ if and only if $G$ is any one of the following graphs where, (a) both $H_{1}$ and $H_{2}$ are complete graphs.
(b) $H_{1}=K_{2}$ or a connected graph with diameter two in which there exist at least one pair of adjacent vertices with no path of length two between them and $H_{2}$ is a disconnected graph in which there exist at least one component with an isolated vertex.

Proof. (a) Let $G \cong K_{n_{1}} \circ K_{n_{2}}$ where $n_{1}, n_{2} \geqslant 2$. Then the deletion of any edge increases the diam(G).
(b) Suppose that $H_{1}=K_{2}$ and $H_{2}$ is a disconnected graph with an isolated vertex $v_{p}$, then $\operatorname{diam}(\mathrm{G})=2$. Let an edge $u_{i} v_{p}-$ $u_{j} v_{p}$, be deleted. There is a path $u_{i} v_{p}-u_{j} v_{q}-u_{i} v_{q}-u_{j} v_{p}$ of length three between them.

Let $H_{1}$ be a connected graph with diameter two in which the adjacent vertices $u_{r}$, $u_{s}$ have no path of length two between them and $H_{2}$ be a disconnected graph with an isolated vertex $v_{p}$, then $\operatorname{diam}(\mathrm{G})=2$. Let an edge $u_{r} v_{p}-u_{s} v_{p}$, be deleted. There is a path $u_{r} v_{p}-u_{s} v_{q}-u_{r} v_{q}-u_{s} v_{p}$ of length three between them.

Conversely suppose that $D^{1}(G)=1$.
Let $u_{x}, u_{y}$ be a pair of diametral vertices in $H_{1}$, by a path $u_{x}-u_{x+1}-u_{x+2}-\ldots-u_{y-1}-u_{y}$ and $v_{w}, v_{z}$ be a pair of diametral vertices in $H_{2}$, by a path $v_{w}-v_{w+1}-v_{w+2}-\ldots-v_{z-1}-v_{z}$.

Suppose that $H_{1}$ is a complete graph and $H_{2}$ is any connected graph, then $\operatorname{diam}(G) \leqslant 2$.

Let an edge $u_{i} v_{p}-u_{i} v_{q}$ or $u_{i} v_{p}-u_{j} v_{p}$ or $u_{i} v_{p}-u_{j} v_{q}$, be deleted. There exist at least two paths of length two between these pairs of vertices. Also, the distance between any two other vertices is not affected by the removal of these edges. Thus to increase the $\operatorname{diam}(\mathrm{G})$ by one, $H_{2}$ should be a complete graph. This proves (a).

Suppose that $H_{1}$ is a connected graph.

Let an edge $u_{i} v_{w}-u_{j} v_{w}$, be deleted. If $H_{2}$ is any connected graph, then there exist at least $\kappa\left(H_{2}\right)+1$ paths $u_{x} v_{w}-$ $u_{x+1} v_{z} \ldots u_{y-1} v_{z}-u_{y} v_{w}$ of length $\operatorname{diam}\left(H_{1}\right)$ between $u_{x} v_{w}$ and $u_{y} v_{w}$ in $G$ where $z \in\left\{1,2, \ldots, n_{2}\right\}$. Thus, when $H_{2}$ is a connected graph, at least two edges should be deleted to increase the diam(G). Hence, it is clear that $H_{2}$ should be a disconnected
2.3. Diameter variability of the lexicographic product of graphs
graph.

Now, if $H_{2}$ is a disconnected graph without an isolated vertex, then there exist at least two paths of length $\operatorname{diam}(\mathrm{G})$ between a pair of diametral vertices $u_{x} v_{w}$ and $u_{y} v_{w}$ in $G$. Thus, at least two edges should be deleted to increase the diam(G). Hence, $H_{2}$ is a disconnected graph in which there exist at least one component with an isolated vertex.

If $\operatorname{diam}\left(H_{1}\right) \geqslant 3$, then the deletion of an edge will not increase the $\operatorname{diam}(\mathrm{G})$. There is a path of length at most three between each pair of vertices. Hence, $H_{1}$ is any connected graph with $\operatorname{diam}\left(H_{1}\right) \leqslant 2$.

Let $H_{1}$ be a complete graph with $n_{1}>2$.

Since $n_{1}>2$ there exist at least two paths of length two between each pair of vertices in $G$. Thus, the deletion of an edge from $G$ does not increase the $\operatorname{diam}(G)$. Hence, $n_{1}=2$.

Let $\operatorname{diam}\left(H_{1}\right)=2$.

Let an edge $u_{i} v_{p}-u_{j} v_{p}$, be deleted. Then the diam(G) increases only if $u_{i}$ and $u_{j}$ have no path of length two between
them in $H_{1}$. Otherwise, at least two edges should be deleted to increase the $\operatorname{diam}(G)$. Also, the distance between any two other vertices is not affected by the removal of these edges. Hence, $H_{1}$ should be a connected graph with diameter two in which there exist at least one pair of adjacent vertices with no path of length two between them.

This proves (b).

Corollary 2.3.7. $G \cong H_{1} \circ H_{2}$ is diameter minimal if and only if $G$ is any one of the following graphs where,
(a) both $H_{1}$ and $H_{2}$ are complete graphs.
(b) $H_{1}=K_{2}$ or a connected graph with diameter two in which there is no path of length two between any two adjacent vertices in $H_{1}$ and $H_{2}$ is a totally disconnected graph.

Proof. (a) Let $G=K_{n_{1}} \circ K_{n_{2}}$. Then $G$ is diameter minimal.
(b) Suppose that $H_{1}$ is a $K_{2}$ and $H_{2}$ is a totally disconnected graph, then $\operatorname{diam}(G)=2$. Let an edge $u_{i} v_{p}-u_{j} v_{p}$ or $u_{i} v_{p}-u_{j} v_{q}$, be deleted. Then there is a path $u_{i} v_{p}-u_{j} v_{q}-u_{i} v_{q}-u_{j} v_{p}$ or $u_{i} v_{p}-u_{j} v_{p}-u_{i} v_{q}-u_{j} v_{q}$ of length three between each pair of vertices. Thus, the deletion of any edge increases the diam $(\mathrm{G})$.
2.3. Diameter variability of the lexicographic product of graphs

Suppose that $H_{1}$ is a connected graph with diameter two in which there is no path of length two between any two adjacent vertices in $H_{1}$ and $H_{2}$ is a totally disconnected graph, then $\operatorname{diam}(\mathrm{G})=2$. Let an edge $u_{i} v_{p}-u_{j} v_{p}$ or $u_{i} v_{p}-u_{j} v_{q}$, be deleted. There is a path of length three between these pairs of vertices. Thus, the deletion of any edge increases the diam(G).

Hence, $G$ is diameter minimal.

Conversely suppose that $G$ is diameter minimal. In Theorem 2.3.6 we have characterized the lexicographic product of graphs whose diameter increases by the deletion of a single edge. Hence, we need to prove the theorem only for such $G$ s.

Let $G \cong K_{n_{1}} \circ K_{n_{2}}$. Then, clearly $G$ is diameter minimal.

Suppose that $H_{1}=K_{2}$ and $H_{2}$ is a disconnected graph in which there exist at least one component with an isolated vertex.

Let an edge $u_{i} v_{p}-u_{i} v_{q}$ where $v_{p}, v_{q}$ are not isolated vertices in $H_{2}$, be deleted. Since $v_{p}, v_{q}$ are not isolated vertices there is a path of length two between $u_{i} v_{p}$ and $u_{i} v_{q}$ in $G$. Hence, if $H_{2}$ contains any pair of adjacent vertices, the deletion of that edge will not increase the diam(G). Thus, $H_{2}$ is a totally disconnected
graph.

Suppose that $H_{1}$ is a connected graph with diameter two in which at least one pair of adjacent vertices have no path of length two between them and $H_{2}$ is a disconnected graph in which there exist at least one component with an isolated vertex.

As in the previous case, if $H_{2}$ contains any pair of adjacent vertices, the deletion of that edge will not increase the diam(G). Hence, $H_{2}$ is a totally disconnected graph.

Let an edge $u_{i} v_{p}-u_{j} v_{p}$ where the adjacent vertices $u_{i}$ and $u_{j}$ have a path of length two in $H_{1}$, be deleted. If any two adjacent vertices in $H_{1}$ have a path of length two between them, then the deletion of an edge will not increase the diam(G). Thus, $H_{1}$ is a connected graph with diameter two in which there is no path of length two between any two adjacent vertices in $H_{1}$.

Theorem 2.3.8. Let $G \cong H_{1} \circ H_{2}$.
Then $D^{1}(G) \leqslant \alpha n_{2}$ where $\alpha$ is the minimum number of edge disjoint paths of length diam $\left(H_{1}\right)$ between any two vertices in $H_{1}$.

Proof. Follows from Theorem 2.2.6.
$\qquad$ graphs

Theorem 2.3.9. Let $G \cong H_{1} \circ H_{2}$. Then $D^{-1}(G)=1$ if and only if $G$ is any one of the following graphs where, (a) $H_{2}$ has a universal vertex and $H_{1}$ is a connected graph with $\operatorname{diam}\left(H_{1}\right) \geqslant 4$ and $D^{-2}\left(H_{1}\right)=1$ when an edge is added between a diametral vertex and any other vertex of $H_{1}$.
(b) $H_{2}$ is any graph and $H_{1}$ is a connected graph with $\operatorname{diam}\left(H_{1}\right) \geqslant 4$ and $D^{-1}\left(H_{1}\right)=1$ when an edge is added between the diametral vertices or between any two other vertices of $H_{1}$.

Proof. Follows from Theorem 2.2.7.

Corollary 2.3.10. There does not exist a graph $G \cong H_{1} \circ H_{2}$ such that $G$ is diameter maximal.

## Chapter 3

## Diameter vulnerability of the product graphs

In the design of an interconnection network, another fundamental consideration is the reliability of the network, which is characterized by the connectivity of the network. If some processors or links are faulty the efficiency of the network may be affected. Vulnerability is a measure of the ability of the system to withstand vertex or edge faults and maximum routing delay. Diameter can be used to evaluate the maximum delay in routing.

[^1]These problems deal with how the remaining processors can still communicate with a reasonable efficiency [66].

### 3.1 Diameter vulnerability of the product graphs

Theorem 3.1.1. Let $G \cong H_{1} \square H_{2}$, where $H_{1}$ is a complete graph and $H_{2}$ is a connected graph with $\kappa^{\prime}\left(H_{2}\right)=\delta\left(H_{2}\right)$. Then $f^{\prime}(G)=\operatorname{diam}(G)+1$.

Proof. Case 1: $G \cong K_{n_{1}} \square K_{n_{2}}$.

Then $\kappa^{\prime}(G)=n_{1}+n_{2}-2$ and $\operatorname{diam}(\mathrm{G})=2$. We shall prove the theorem by considering the following sub cases where the fault occurs on $F \subseteq E(G)$.
(a) Let $F$ be the set of edges of the form $u_{i} v_{p}-u_{x} v_{p}$ where $i, x \in\left\{1,2, \ldots, n_{1}\right\}$.

Let the $\kappa^{\prime}(G)-1$ edges be deleted from $F$. There is a path $u_{i} v_{p}-u_{i} v_{q}-u_{j} v_{q}-u_{j} v_{p}$ of length three between these pairs of vertices. Also, the distance between any two other vertices is
not affected by the removal of these edges. Hence, $\operatorname{diam}(G)=3$.
(b) Let $F$ be the set of edges of the form $u_{i} v_{p}-u_{i} v_{q}$ where $p, q \in\left\{1,2, \ldots, n_{2}\right\}$.

Let the $\kappa^{\prime}(G)-1$ edges be deleted from $F$. There is a path of length three between these pairs of vertices. Also, the distance between any two other vertices is not affected by the removal of these edges.
(c) Let $F$ be any arbitrary collection of edges.

Consider a pair of non adjacent vertices $u_{i} v_{p}$ and $u_{j} v_{q}$ in $G$. Let the $n_{1}+n_{2}-3$ edges adjacent to the vertex $u_{i} v_{p}$ except $u_{x} v_{p}$, be deleted. Then, $d\left(u_{i} v_{p}, u_{j} v_{q}\right)=3$ by a path $u_{i} v_{p}-$ $u_{x} v_{p}-u_{x} v_{q}-u_{j} v_{q}$ and $d\left(u_{i} v_{p}, u_{i} v_{r}\right)=d\left(u_{i} v_{p}, u_{y} v_{p}\right)=2$. Also, the distance between any two other vertices is not affected by the removal of these edges.

Hence, $f^{\prime}(G)=3$.

Case 2: $G \cong K_{n_{1}} \square H_{2}$, where $H_{2}$ is a not complete graph.

Then $\kappa^{\prime}(G)=n_{1}-1+\kappa^{\prime}\left(H_{2}\right)$ and $\operatorname{diam}(\mathrm{G})=1+\operatorname{diam}\left(H_{2}\right)$. Let $v_{w}, v_{z}$ be a pair of diametral vertices in $H_{2}$, by a path
$v_{w}-v_{w+1}-v_{w+2}-\ldots-v_{z-1}-v_{z}$. We shall prove the theorem by considering the following sub cases.
(a) Let $F$ be the set of edges of the form $u_{i} v_{p}-u_{x} v_{p}$ where $i, x \in\left\{1,2, \ldots, n_{1}\right\}$.

Let the $\kappa^{\prime}(G)-1$ edges be deleted from $F$. There is a path of length three between these pairs of vertices. Also, the distance between any two other vertices in $G$ is not affected by the removal of these edges.
(b) Let $F$ be the set of edges of the form $u_{i} v_{p}-u_{i} v_{q}$ where $p, q \in\left\{1,2, \ldots, n_{2}\right\}$.

Consider a pair of vertices $u_{i} v_{w}$ and $u_{i} v_{z}$ in $G$. Let the $\kappa^{\prime}(G)-1$ edges be deleted from $F$. Then, $d\left(u_{i} v_{w}, u_{i} v_{z}\right)=\operatorname{diam}(\mathrm{G})+1$ by a path $u_{i} v_{w}-u_{j} v_{w}-u_{j} v_{w+1}-\ldots-u_{j} v_{z-1}-u_{j} v_{z}-u_{i} v_{z}$ where $d\left(u_{i} v_{w}, u_{j} v_{w}\right)=d\left(u_{i} v_{z}, u_{j} v_{z}\right)=1, d\left(u_{j} v_{w}, u_{j} v_{z}\right)=\operatorname{diam}\left(H_{2}\right)$. Also, $d\left(u_{i} v_{w}, u_{i} v_{p}\right)=3$ by a path $u_{i} v_{w}-u_{j} v_{w}-u_{j} v_{p}-u_{i} v_{p}$. The distance between any two other vertices is not affected by the removal of these edges.
(c) Let $F$ be any arbitrary collection of edges.

Consider a pair of vertices $u_{i} v_{w}$ and $u_{i} v_{z}$ in $G$. Let the $\kappa^{\prime}(G)-1$ edges adjacent to the vertex $u_{i} v_{z}$ except $u_{j} v_{z}$, be deleted. Then, $d\left(u_{i} v_{w}, u_{i} v_{z}\right)=\operatorname{diam}(\mathrm{G})+1$ by a path $u_{i} v_{w}-$ $u_{j} v_{w}-u_{j} v_{w+1}-\ldots-u_{j} v_{z-1}-u_{j} v_{z}-u_{i} v_{z}$ where $d\left(u_{i} v_{w}, u_{j} v_{w}\right)=1$, $d\left(u_{j} v_{w}, u_{j} v_{z}\right)=\operatorname{diam}\left(H_{2}\right)$ and $d\left(u_{i} v_{z}, u_{j} v_{z}\right)=1$. Also, $d\left(u_{i} v_{z}, u_{i} v_{p}\right)=3$ and $d\left(u_{i} v_{w}, u_{x} v_{w}\right)=3$.

Hence, $f^{\prime}(G)=\operatorname{diam}(G)+1$.

Theorem 3.1.2. Let $G \cong H_{1} \square H_{2}$ be a connected graph. Then $f^{\prime}(G) \leqslant \max \left\{f^{\prime}\left(H_{1}\right)+2 \operatorname{diam}\left(H_{2}\right), f^{\prime}\left(H_{2}\right)+2 \operatorname{diam}\left(H_{1}\right)\right\}$.

Proof. Let $u_{x}, u_{y}$ be a pair of diametral vertices in $H_{1}$, by a path $u_{x}-u_{x+1}-u_{x+2}-\ldots-u_{y-1}-u_{y}$ and $v_{w}, v_{z}$ be a pair of diametral vertices in $H_{2}$, by a path $v_{w}-v_{w+1}-v_{w+2}-\ldots-v_{z-1}-$ $v_{z}$. We shall prove the theorem by considering the following cases.
(a) Let $F$ be the set of edges of the form $u_{i} v_{p}-u_{i} v_{q}$ where $p, q \in\left\{1,2, \ldots, n_{2}\right\}$.

Consider a pair of vertices $u_{i} v_{w}, u_{i} v_{z}$ in $G$. Let the $\kappa^{\prime}(G)-1$ edges be deleted from $F$. Then, $d\left(u_{i} v_{w}, u_{i} v_{z}\right)=\operatorname{diam}\left(H_{2}\right)+2$
by a path $u_{i} v_{w}-u_{j} v_{w}-u_{j} v_{w+1}-\ldots-u_{j} v_{z}-u_{i} v_{z}$ where $d\left(u_{i} v_{w}, u_{j} v_{w}\right)=1, d\left(u_{j} v_{w}, u_{j} v_{z}\right)=\operatorname{diam}\left(H_{2}\right), d\left(u_{j} v_{z}, u_{i} v_{z}\right)=1$.

Also, the distance between any two other vertices is not affected by the removal of these edges.
(b) Let $F$ be the set of edges of the form $u_{i} v_{p}-u_{j} v_{p}$ where $i, j \in\left\{1,2, \ldots, n_{1}\right\}$.

Consider a pair of vertices $u_{x} v_{p}, u_{y} v_{p}$ in $G$. Let the $\kappa^{\prime}(G)-1$ edges be deleted from $F$. Then, $d\left(u_{x} v_{p}, u_{y} v_{p}\right)=\operatorname{diam}\left(H_{1}\right)+2$. Also, the distance between any two other vertices is not affected by the removal of these edges.
(c) Let $F$ be any arbitrary collection of edges.

Consider a pair of diametral vertices $u_{x} v_{w}$ and $u_{y} v_{z}$ in $G$. Let the $\kappa^{\prime}(G)-1$ edges adjacent to the vertex $u_{y-1} v_{z}$ except $u_{y-1} v_{y}$, be deleted. Then, $d\left(u_{x} v_{w}, u_{y} v_{z}\right)=\operatorname{diam}(\mathrm{G})+1$ by a path $u_{x} v_{w}-u_{x+1} v_{w}-\ldots-u_{y} v_{w}-\ldots-u_{y} v_{z}-u_{y-1} v_{z}$ where $d\left(u_{x} v_{w}, u_{y} v_{w}\right)=\operatorname{diam}\left(H_{1}\right), d\left(u_{y} v_{w}, u_{y} v_{z}\right)=\operatorname{diam}\left(H_{2}\right)$ and $d\left(u_{y} v_{z}, u_{y-1} v_{z}\right)=1$. Also, $d\left(u_{y-1} v_{z}, u_{p} v_{z}\right)=d\left(u_{y-1} v_{z}, u_{y-1} v_{q}\right)=3$. Thus, the deletion of $\kappa^{\prime}(G)-1$ edges increases the diam $(\mathrm{G})$ by one.

Now, consider a pair of vertices $u_{a} v_{w}$ and $u_{b} v_{w}$ in $G$. Let the edges $u_{i} v_{p}-u_{j} v_{p}$ where $\left\{u_{i}-u_{j}\right\}$ is a collection of $\kappa^{\prime}\left(H_{1}\right)$ edges which form an edge cut of $H_{1}$ and $p \in\left\{1,2, \ldots, n_{2}-1\right\}$, be deleted. From the $H_{1}$ - layer at $v_{n_{2}}$ in $G$, we delete only the $\kappa^{\prime}\left(H_{1}\right)-1$ edges, otherwise $G$ becomes disconnected. Then, $d\left(u_{a} v_{n_{2}}, u_{b} v_{n_{2}}\right) \leqslant f^{\prime}\left(H_{1}\right)$ by a path $u_{a} v_{n_{2}}-u_{a+1} v_{n_{2}}-\ldots-$ $u_{b-1} v_{n_{2}}-u_{b} v_{n_{2}}$, since the deletion of $\kappa\left(H_{1}\right)-1$ edges from $H_{1}$ increases the $\operatorname{diam}\left(H_{1}\right)$ to at most $f^{\prime}\left(H_{1}\right)$. Now,
$d\left(u_{a} v_{w}, u_{b} v_{w}\right) \leqslant f^{\prime}\left(H_{1}\right)+2 \operatorname{diam}\left(H_{2}\right)$ by a path $u_{a} v_{w}-u_{a} v_{w+1}-$ $\ldots-u_{a} v_{n_{2}}-u_{a+1} v_{n_{2}}-\ldots-u_{b} v_{n_{2}}-u_{b} v_{r}-\ldots-u_{b} v_{w}$ where $d\left(u_{a} v_{w}, u_{a} v_{n_{2}}\right) \leqslant \operatorname{diam}\left(H_{2}\right), d\left(u_{a} v_{n_{2}}, u_{b} v_{n_{2}}\right) \leqslant f^{\prime}\left(H_{1}\right)$ and $d\left(u_{b} v_{n_{2}}, u_{b} v_{w}\right) \leqslant \operatorname{diam}\left(H_{2}\right)$. Thus, the deletion of $\kappa^{\prime}(G)-1$ edges increases the $\operatorname{diam}(\mathrm{G})$ by $f^{\prime}\left(H_{1}\right)+2 \operatorname{diam}\left(H_{2}\right)$.

Similarly, if the $\kappa^{\prime}(G)-1$ edges $u_{p} v_{a}-u_{p} v_{b}$ where $\left\{v_{a}-v_{b}\right\}$ is a collection of $\kappa^{\prime}\left(H_{2}\right)$ edges which form an edge cut of $H_{2}$ and $p \in\left\{1,2, \ldots, n_{1}\right\}$, are deleted then, the $\operatorname{diam}(\mathrm{G})$ increases by $f^{\prime}\left(H_{2}\right)+2 \operatorname{diam}\left(H_{1}\right)$.

Hence, $f^{\prime}(G) \leqslant \max \left\{f^{\prime}\left(H_{1}\right)+2 \operatorname{diam}\left(H_{2}\right), f^{\prime}\left(H_{2}\right)+2 \operatorname{diam}\left(H_{1}\right)\right\}$.

## Illustration of Theorem 3.1.2

G

Fig 3.1: A graph $G$ with $f^{\prime}(G)=f^{\prime}\left(H_{1}\right)+2 \operatorname{diam}\left(H_{2}\right)=7$.

Theorem 3.1.3. Let $G \cong H_{1} \boxtimes H_{2}$ be a connected graph. Then $f^{\prime}(G) \leqslant \max \left\{f^{\prime}\left(H_{1}\right)+\operatorname{diam}\left(H_{2}\right), f^{\prime}\left(H_{2}\right)+\operatorname{diam}\left(H_{1}\right)\right\}$.

Proof. Let $G \cong H_{1} \boxtimes H_{2}$ be a connected graph. Then $\kappa^{\prime}(G)=\min \left\{\kappa^{\prime}\left(H_{1}\right)\left(\left|V\left(H_{2}\right)\right|+2 E\left(H_{2}\right)\right), \kappa^{\prime}\left(H_{2}\right)\left(\left|V\left(H_{1}\right)\right|+2 E\left(H_{1}\right)\right)\right.$, $\left.\delta\left(H_{1} \boxtimes H_{2}\right)\right\}$. Let $u_{x}, u_{y}$ be a pair of diametral vertices in $H_{1}$, by a path $u_{x}-u_{x+1}-u_{x+2}-\ldots-u_{y-1}-u_{y}$ and $v_{w}, v_{z}$ be a pair of diametral vertices in $H_{2}$, by a path $v_{w}-v_{w+1}-v_{w+2}-\ldots-v_{z-1}-v_{z}$. We shall prove the theorem by considering the following cases.
(a) Let $F$ be the set of edges of the form $u_{i} v_{k}-u_{j} v_{k}$ where $i, j \in\left\{1,2, \ldots, n_{1}\right\}$.

Consider a pair of vertices $u_{x} v_{k}$ and $u_{y} v_{k}$ in $G$. Let the $\kappa^{\prime}(G)-1$ edges be deleted from $F$. Then, $d\left(u_{x} v_{k}, u_{y} v_{k}\right)=\operatorname{diam}\left(H_{1}\right)$ by a path $u_{x} v_{k}-u_{x+1} v_{k+1}-u_{x+2} v_{k+1}-\ldots-u_{y-1} v_{k+1}-u_{y} v_{k}$.
(b) Let $F$ be the set of edges of the form $u_{i} v_{j}-u_{i} v_{k}$ where $j, k \in\left\{1,2, \ldots, n_{2}\right\}$.

Consider a pair of vertices $u_{i} v_{w}$ and $u_{i} v_{z}$ in $G$. Let the $\kappa^{\prime}(G)-1$ edges be deleted from $F$. Then, $d\left(u_{i} v_{w}, u_{i} v_{z}\right)=\operatorname{diam}\left(H_{2}\right)$ by a path $u_{i} v_{w}-u_{i+1} v_{w+1}-u_{i+1} v_{w+2}-\ldots u_{i+1} v_{z-1}-u_{i} v_{z}$.
(c) Let $F$ be any arbitrary collection of edges.

Consider a pair of diametral vertices $u_{x} v_{w}$ and $u_{y} v_{w}$ in $G$. Let the $\kappa^{\prime}(G)-1$ edges adjacent to the vertex $u_{x} v_{w}$ except $u_{x} v_{w+1}$, be deleted. The distance between $u_{x} v_{w}$ and $u_{y} v_{w}$ increases by a path $u_{x} v_{w}-u_{x} v_{w+1}-u_{x+1} v_{w}-\ldots-u_{y} v_{w}$ where $d\left(u_{x} v_{w}, u_{x+1} v_{w}\right)=2$ and $d\left(u_{x+1} v_{w}, u_{y} v_{w}\right)=\operatorname{diam}\left(H_{1}\right)-1$. Also, the distance between any two other vertices is not affected by the removal of these edges.

Now, consider a pair of vertices $u_{a} v_{w}$ and $u_{b} v_{w}$ in $G$. Let the edges $u_{i} v_{r}-u_{j} v_{r}, u_{i} v_{p}-u_{j} v_{q}$ where $\left\{u_{i}-u_{j}\right\}$ is a collection of $\kappa^{\prime}\left(H_{1}\right)$ edges which form an edge cut of $H_{1}$ and $r \in\left\{1,2, \ldots, n_{2}-1\right\}$,
$q \neq p \in\left\{1,2, \ldots, n_{2}\right\}$ and $v_{q} \mathrm{~s}$ are the vertices adjacent to $v_{p}$ in $H_{2}$, be deleted. From the $H_{1}$ - layer at $v_{n_{2}}$ in $G$, we delete only the $\kappa^{\prime}\left(H_{1}\right)-1$ edges, otherwise $G$ becomes disconnected. Then, $d\left(u_{a} v_{n_{2}}, u_{b} v_{n_{2}}\right) \leqslant f^{\prime}\left(H_{1}\right)$ by a path $u_{a} v_{n_{2}}-$ $u_{a+1} v_{n_{2}}-\ldots-u_{b-1} v_{n_{2}}-u_{b} v_{n_{2}}$, since the deletion of $\kappa^{\prime}\left(H_{1}\right)-1$ edges from $H_{1}$ increases the $\operatorname{diam}\left(H_{1}\right)$ to at most $f^{\prime}\left(H_{1}\right)$. Now, $d\left(u_{a} v_{w}, u_{b} v_{w}\right) \leqslant f^{\prime}\left(H_{1}\right)+\operatorname{diam}\left(H_{2}\right)$ by a path $u_{a} v_{w}-u_{a} v_{w+1}-$ $\ldots-u_{a} v_{n_{2}}-u_{a+1} v_{n_{2}}-\ldots-u_{b-1} v_{w+1}-u_{b} v_{w}$ where $d\left(u_{a} v_{w}, u_{a} v_{n_{2}}\right) \leqslant \operatorname{diam}\left(H_{2}\right)$ and $d\left(u_{a} v_{n_{2}}, u_{b} v_{w}\right) \leqslant f^{\prime}\left(H_{1}\right)$. Thus, the distance between any two other vertices is at most $f^{\prime}\left(H_{1}\right)+\operatorname{diam}\left(H_{2}\right)$.

Similarly, if the $\kappa^{\prime}(G)-1$ edges $u_{x} v_{p}-u_{x} v_{q}, u_{x} v_{p}-u_{i} v_{r}$ where $x \in\left\{1,2, \ldots, n_{1}\right\}, u_{i}$ s are the vertices adjacent to $u_{x}$ in $H_{1}$ and $\left\{v_{p}-v_{q}\right\}$ is a collection of $\kappa^{\prime}\left(H_{2}\right)$ edges which form an edge cut of $H_{2}$, are deleted then, the diam $(\mathrm{G})$ increases by $f^{\prime}\left(H_{2}\right)+\operatorname{diam}\left(H_{1}\right)$.

Hence, $f^{\prime}(G) \leqslant \max \left\{f^{\prime}\left(H_{1}\right)+\operatorname{diam}\left(H_{2}\right), f^{\prime}\left(H_{2}\right)+\operatorname{diam}\left(H_{1}\right)\right\}$.

## Illustration of Theorem 3.1.3

Fig 3.2: A graph $G$ with $f^{\prime}(G)=\max \left\{f^{\prime}\left(H_{1}\right)+\operatorname{diam}\left(H_{2}\right)\right.$, $\left.f^{\prime}\left(H_{2}\right)+\operatorname{diam}\left(H_{1}\right)\right\}=5$.

Theorem 3.1.4. Let $G \cong H_{1} \circ H_{2}$ be a connected graph with $n_{1}, n_{2} \geqslant 3$. Then $f^{\prime}(G) \leqslant f^{\prime}\left(H_{1}\right)+\operatorname{diam}\left(H_{2}\right)$.

Proof. Let $G \cong H_{1} \circ H_{2}$ be a connected graph. Then the $\kappa^{\prime}(G)=\min \left\{\kappa^{\prime}\left(H_{1}\right) n_{2}^{2}, \delta\left(H_{2}\right)+\delta\left(H_{1}\right) n_{2}\right\}$ and $\operatorname{diam}(\mathrm{G})=\operatorname{diam}\left(H_{1}\right)$. Let $u_{x}, u_{y}$ be a pair of diametral vertices in $H_{1}$, by a path $u_{x}-u_{x+1}-u_{x+2}-\ldots-u_{y-1}-u_{y}$ and $v_{w}, v_{z}$ be a pair of diametral vertices in $H_{2}$, by a path $v_{w}-v_{w+1}-v_{w+2}-\ldots-v_{z-1}-v_{z}$. We shall prove the theorem by considering the following cases.
(a) Let $F$ be the set of edges of the form $u_{i} v_{k}-u_{j} v_{k}$ where $i, j \in\left\{1,2, \ldots, n_{1}\right\}$.

Consider a pair of vertices $u_{x} v_{k}$ and $u_{y} v_{k}$ in $G$. Let the
$\kappa^{\prime}(G)-1$ edges be deleted from $F$. Then, $d\left(u_{x} v_{k}, u_{y} v_{k}\right)=\operatorname{diam}(G)$ by a path $u_{x} v_{k}-u_{x+1} v_{k+1}-u_{x+2} v_{k+1}-\ldots-u_{y-1} v_{k+1}-u_{y} v_{k}$.
(b) Let $F$ be the set of edges of the form $u_{i} v_{j}-u_{i} v_{k}$ where $j, k \in\left\{1,2, \ldots, n_{2}\right\}$.

Let the $\kappa^{\prime}(G)-1$ edges be deleted from $F$. There is a path $u_{i} v_{j}-u_{i+1} v_{j}-u_{i} v_{k}$ of length two between $u_{i} v_{j}$ and $u_{i} v_{k}$ in $G$. Thus, the diam(G) remains the same.
(c) Let $F$ be any arbitrary collection of edges.

Consider a pair of diametral vertices $u_{x} v_{w}$ and $u_{y} v_{w}$ in $G$. Let the $\kappa^{\prime}(G)-1$ edges adjacent to the vertex $u_{x} v_{w}$ except $u_{x} v_{w+1}$, be deleted. Then, $d\left(u_{x} v_{w}, u_{y} v_{w}\right)=\operatorname{diam}(G)+1$ by a path $u_{x} v_{w}-$ $u_{x} v_{w+1}-u_{x+1} v_{w}-\ldots-u_{y} v_{w}$ where $d\left(u_{x} v_{w}, u_{x+1} v_{w}\right)=2$ and $d\left(u_{x+1} v_{w}, u_{y} v_{w}\right)=\operatorname{diam}(G)-1$.

Consider a pair of diametral vertices $u_{x} v_{w}$ and $u_{y} v_{z}$ in $G$. Since we have already considered the case of the deletion of edges from $F$ of the form $u_{i} v_{k}-u_{j} v_{k}$ where $i, j \in\left\{1,2, \ldots, n_{1}\right\}$ and $u_{i} v_{j}-u_{i} v_{k}$ where $j, k \in\left\{1,2, \ldots, n_{2}\right\}$ in (a) and (b) respectively, there will exist at least one edge (say) $u_{p} v_{r}-u_{q} v_{r}$ for each $r \in\left\{1,2, \ldots, n_{2}\right\}$. Thus, there exist a path $u_{x} v_{w}-u_{x+1} v_{p}-$
$u_{x+2} v_{q}-\ldots-u_{y} v_{z}$ of length $\operatorname{diam}(\mathrm{G})$ between $u_{x} v_{w}, u_{y} v_{z}$ in $G$.

Consider a pair of vertices $u_{a} v_{w}, u_{b} v_{w}$ in $G$. Let the edges $u_{i} v_{r}-u_{j} v_{r}, u_{i} v_{p}-u_{j} v_{q}$ where $\left\{u_{i}-u_{j}\right\}$ is a collection of $\kappa^{\prime}\left(H_{1}\right)$ edges which form an edge cut of $H_{1}$ and $r \in\left\{1,2, \ldots, n_{2}-1\right\}$, $q \neq p \in\left\{1,2, \ldots, n_{2}\right\}$, be deleted. From the $H_{1}$ - layer at $v_{n_{2}}$ in $G$, we delete only the $\kappa^{\prime}\left(H_{1}\right)-1$ edges, otherwise $G$ becomes disconnected. Then, $d\left(u_{a} v_{n_{2}}, u_{b} v_{n_{2}}\right) \leqslant f^{\prime}\left(H_{1}\right)$ by a path $u_{a} v_{n_{2}}-u_{a+1} v_{n_{2}}-\ldots-u_{b-1} v_{n_{2}}-u_{b} v_{n_{2}}$, since the deletion of $\kappa\left(H_{1}\right)-1$ edges from $H_{1}$ increases the $\operatorname{diam}\left(H_{1}\right)$ to at most $f^{\prime}\left(H_{1}\right)$. Now, $d\left(u_{a} v_{w}, u_{b} v_{w}\right) \leqslant f^{\prime}\left(H_{1}\right)+\operatorname{diam}\left(H_{2}\right)$ by a path $u_{a} v_{w}-u_{a} v_{w+1}-\ldots-u_{a} v_{n_{2}}-u_{a+1} v_{n_{2}}-\ldots-u_{b-1} v_{n_{2}}-u_{b} v_{w}$ where $d\left(u_{a} v_{w}, u_{a} v_{n_{2}}\right) \leqslant \operatorname{diam}\left(H_{2}\right)$ and $d\left(u_{a} v_{n_{2}}, u_{b} v_{w}\right) \leqslant f^{\prime}\left(H_{1}\right)$. Hence the result.

## Illustration of Theorem 3.1.4

Fig 3.3: A graph $G$ with $f^{\prime}(G)=f^{\prime}\left(H_{1}\right)+\operatorname{diam}\left(H_{2}\right)=4$.

We shall now discuss some results on the notion of fault diameter in the product graphs.

Theorem 3.1.5. Let $G \cong H_{1} \square H_{2}$ be a connected graph. Then $f(G) \leqslant \max \left\{f\left(H_{1}\right)+2 \operatorname{diam}\left(H_{2}\right), f\left(H_{2}\right)+2 \operatorname{diam}\left(H_{1}\right)\right\}$.

Proof. Let $u_{x}, u_{y}$ be a pair of diametral vertices in $H_{1}$, by a path $u_{x}-u_{x+1}-u_{x+2}-\ldots-u_{y-1}-u_{y}$ and $v_{w}, v_{z}$ be a pair of diametral vertices in $H_{2}$, by a path $v_{w}-v_{w+1}-v_{w+2}-\ldots-v_{z-1}-$ $v_{z}$. We shall prove the theorem by considering the following cases where the fault occurs on $S \subseteq V(G)$.
(a) Let $S$ be the set of vertices of the form $u_{i} v_{p}$ where $p \in\left\{1,2, \ldots, n_{2}\right\}$.

Consider a pair of vertices $u_{i} v_{w}, u_{i} v_{z}$ in $G$. Let the $\kappa(G)-1$ vertices from $S$ be deleted. Then, $d\left(u_{i} v_{w}, u_{i} v_{z}\right)=\operatorname{diam}\left(H_{2}\right)+2$ by a path $u_{i} v_{w}-u_{j} v_{w}-u_{j} v_{w+1}-\ldots-u_{j} v_{z}-u_{i} v_{z}$ where $d\left(u_{i} v_{w}, u_{j} v_{w}\right)=1, d\left(u_{j} v_{w}, u_{j} v_{z}\right)=\operatorname{diam}\left(H_{2}\right), d\left(u_{j} v_{z}, u_{i} v_{z}\right)=1$. Now, $d\left(u_{y} v_{w}, u_{z} v_{w}\right) \leqslant f\left(H_{1}\right)$, since the deletion of the vertex $u_{i}$ from $H_{1} \operatorname{increases}$ the $\operatorname{diam}\left(H_{1}\right)$ to at most $f\left(H_{1}\right)$. Hence, $f(G) \leqslant \max \left\{\operatorname{diam}\left(H_{2}\right)+2, f\left(H_{1}\right)\right\}$.
(b) Let $S$ be the set of vertices of the form $u_{j} v_{p}$ where
$j \in\left\{1,2, \ldots, n_{1}\right\}$.

Consider a pair of vertices $u_{x} v_{p}, u_{y} v_{p}$ in $G$. Let the $\kappa(G)-1$ vertices from $S$ be deleted. Then, $d\left(u_{x} v_{p}, u_{y} v_{p}\right) \leqslant \operatorname{diam}\left(H_{1}\right)+2$. Now, $d\left(u_{y} v_{w}, u_{y} v_{z}\right) \leqslant f\left(H_{2}\right)$, since the deletion of the vertex $v_{p}$ from $H_{2}$ increases the $\operatorname{diam}\left(H_{2}\right)$ to at most $f\left(H_{2}\right)$. Hence, $f(G) \leqslant \max \left\{\operatorname{diam}\left(H_{1}\right)+2, f\left(H_{2}\right)\right\}$.
(c) Let $S$ be any arbitrary collection of vertices.

Consider a pair of diametral vertices $u_{x} v_{w}$ and $u_{y} v_{z}$ in $G$. Let the $\kappa(G)-1$ vertices adjacent to the vertex $u_{y-1} v_{z}$ except $u_{y} v_{z}$ in $G$, be deleted. Then, $d\left(u_{x} v_{w}, u_{y} v_{z}\right)=\operatorname{diam}(G)+1$ by a path $u_{x} v_{w}-u_{x+1} v_{w}-\ldots-u_{y} v_{w}-\ldots-u_{y} v_{z}-u_{y-1} v_{z}$ where $d\left(u_{x} v_{w}, u_{y} v_{w}\right)=\operatorname{diam}\left(H_{1}\right), d\left(u_{y} v_{w}, u_{y} v_{z}\right)=\operatorname{diam}\left(H_{2}\right)$ and $d\left(u_{y} v_{z}, u_{y-1} v_{z}\right)=1$. Also $d\left(u_{y-1} v_{z}, u_{p} v_{z}\right)=d\left(u_{y-1} v_{z}, u_{y-1} v_{q}\right)=3$. Thus, the deletion of $\kappa(G)-1$ vertices increases the diam $(\mathrm{G})$ by one.

Now, consider a pair of vertices $u_{p} v_{w}$ and $u_{q} v_{w}$ in $G$. Let the vertices $u_{i} v_{p}$ where $\left\{u_{i}\right\}$ is a collection of $\kappa\left(H_{1}\right)$ vertices which form a vertex cut of $H_{1}$ and $p \in\left\{1,2,3, \ldots, n_{2}-1\right\}$, be deleted. From the $H_{1}$ - layer at $v_{n_{2}}$ in $G$, we delete only
$\kappa\left(H_{1}\right)-1$ vertices, otherwise $G$ becomes disconnected. Then, $d\left(u_{p} v_{n_{2}}, u_{q} v_{n_{2}}\right) \leqslant f\left(H_{1}\right)$ by a path $u_{p} v_{n_{2}}-u_{p+1} v_{n_{2}}-\ldots-$ $u_{q-1} v_{n_{2}}-u_{q} v_{n_{2}}$, since the deletion of $\kappa\left(H_{1}\right)-1$ vertices from $H_{1}$ increases the $\operatorname{diam}\left(H_{1}\right)$ to at most $f\left(H_{1}\right)$. Now
$d\left(u_{p} v_{w}, u_{q} v_{w}\right) \leqslant f\left(H_{1}\right)+2 \operatorname{diam}\left(H_{2}\right)$ by a path $u_{p} v_{w}-u_{p} v_{w+1}-$ $\ldots-u_{p} v_{n_{2}}-u_{p+1} v_{n_{2}}-\ldots-u_{q} v_{n_{2}}-u_{q} v_{r}-\ldots-u_{y} v_{w}$ where $d\left(u_{p} v_{w}, u_{p} v_{n_{2}}\right) \leqslant \operatorname{diam}\left(H_{2}\right), d\left(u_{p} v_{n_{2}}, u_{q} v_{n_{2}}\right) \leqslant f\left(H_{1}\right)$ and $d\left(u_{q} v_{n_{2}}, u_{q} v_{w}\right) \leqslant \operatorname{diam}\left(H_{2}\right)$.

Similarly, if the $\kappa(G)-1$ vertices $u_{i} v_{p}$ where $i \in\left\{1,2, \ldots, n_{1}\right\}$ and $\left\{v_{p}\right\}$ is a collection of $\kappa\left(H_{2}\right)$ vertices which form a vertex cut of $H_{2}$, are deleted from $G$, then the $\operatorname{diam}(\mathrm{G})$ increases by $f\left(H_{2}\right)+2 \operatorname{diam}\left(H_{1}\right)$. Hence the result.

## Illustration of Theorem 3.1.5

Fig 3.4: A graph $G$ with $f(G)=\max \left\{f\left(H_{1}\right)+2 \operatorname{diam}\left(H_{2}\right)\right.$, $\left.f\left(H_{2}\right)+2 \operatorname{diam}\left(H_{1}\right)\right\}=6$

Theorem 3.1.6. Let $G \cong H_{1} \circ H_{2}$ be a connected graph. Then $f(G) \leqslant \max \left\{f\left(H_{1}\right), f\left(H_{2}\right)\right\}$.

Proof. Let $u_{x}, u_{y}$ be a pair of diametral vertices in $H_{1}$, by a path $u_{x}-u_{x+1}-u_{x+2}-\ldots-u_{y-1}-u_{y}$ and $v_{w}, v_{z}$ be a pair of diametral vertices in $H_{2}$, by a path $v_{w}-v_{w+1}-v_{w+2}-\ldots-v_{z-1}-v_{z}$. We shall prove the theorem by considering the following cases.

Case 1: $G \cong K_{n_{1}} \circ H_{2}$.

Then $\operatorname{diam}(G)=2$ and $\kappa(G)=\left(n_{1}-1\right) n_{2}+\kappa\left(H_{2}\right)$.

Consider a vertex $u_{1} v_{1}$ in $G$. Let the $\kappa(G)-1$ vertices adjacent to the vertex $u_{1} v_{1}$ except $u_{i} v_{r}$, be deleted. Now, let $G^{\prime}$ be the subgraph of $G$ obtained after deleting the $\kappa(G)-1$ vertices, as shown in Fig 3.5 and if $v_{p}$ is not adjacent to $v_{q}$ in $H_{2}$, then $d\left(u_{1} v_{p}, u_{1} v_{q}\right)=2$ by the path $u_{1} v_{p}-u_{i} v_{r}-u_{1} v_{q}$, since $u_{i} \in K_{n_{1}}$. Thus, the diam(G) remains the same.

Now, let the $\kappa(G)-1$ vertices adjacent to $u_{1} v_{1}$ except $u_{1} v_{s}$, be deleted. Let $G^{\prime}$ be the subgraph of $G$ obtained after deleting $\kappa(G)-1$ vertices. Then, $d\left(u_{1} v_{p}, u_{1} v_{q}\right) \leqslant f\left(H_{2}\right)$, since the dele-

Fig 3.5: A subgraph $G^{\prime}$ of $G$.
tion of $\kappa\left(H_{2}\right)-1$ vertices from $H_{2}$ increases the $\operatorname{diam}\left(H_{2}\right)$ to at most $f\left(H_{2}\right)$. Thus $f(G) \leqslant f\left(H_{2}\right)$.

Case 2: $G \cong H_{1} \circ H_{2}$ where $\kappa\left(H_{1}\right)=1$ and $H_{1} \neq K_{2}$.

Then $\operatorname{diam}(\mathrm{G})=\operatorname{diam}\left(H_{1}\right)$ and $\kappa(G)=\kappa\left(H_{1}\right)\left|V\left(H_{2}\right)\right|=n_{2}$. We shall prove the theorem by considering the following sub cases.
(a) Let $S$ be the set of vertices of the form $u_{i} v_{p}$ where $p \in\left\{1,2, \ldots, n_{2}\right\}$.

Consider a pair of diametral vertices $u_{x} v_{a}, u_{y} v_{a}$ in $G$. Let the $n_{2}-1$ vertices except $u_{i} v_{n_{2}}$ from $S$, be deleted. Then, $d\left(u_{x} v_{a}, u_{y} v_{a}\right)=\operatorname{diam}(G)$ by a path $u_{x} v_{a}-u_{x+1} v_{a}-\ldots-u_{i-1} v_{a}-$
$u_{i} v_{n_{2}}-u_{i+1} v_{a}-\ldots-u_{y-1} v_{a}-u_{y} v_{a}$. Thus, the $\operatorname{diam}(\mathrm{G})$ remains the same.
(b) Let $S$ be the set of vertices of the form $u_{i} v_{p}$ where $i \in\left\{1,2, \ldots, n_{1}\right\}$.

Let the $n_{2}-1$ vertices from $S$, be deleted. Clearly, the distance between any two vertices in $G$ is not affected by the removal of these vertices. Thus, the diam(G) remains the same.
(c) Let $S$ be any arbitrary collection of vertices.

Consider a pair of diametral vertices $u_{x} v_{p}$ and $u_{y} v_{q}$ in $G$. Then, $d\left(u_{x} v_{p}, u_{y} v_{q}\right)=\operatorname{diam}\left(H_{1}\right)$ by a path $u_{x} v_{p}-u_{x+1} v_{a}-$ $u_{x+2} v_{b}-\ldots-u_{y} v_{q}$, since we have already considered the case of the deletion of vertices from $S$ of the form $u_{i} v_{p}$ where $i \in\left\{1,2, \ldots, n_{1}\right\}$, there exist at least one vertex (say) $u_{i} v_{j}$ for each $j \in\left\{1,2, \ldots, n_{2}\right\}$ and are adjacent to the vertices $u_{r} v_{p}$ where $p \in\left\{1,2, \ldots, n_{2}\right\}$. Thus, the diam(G) remains the same.

Case 3: $G \cong H_{1} \circ H_{2}$ where $\kappa\left(H_{1}\right)>1$.

We have $\kappa(G) \geqslant 2 n_{2}$. We shall prove the theorem by considering the following sub cases.
(a) Let $S$ be the set of vertices of the form $u_{i} v_{p}$ where $i \in\left\{1,2, \ldots, n_{1}\right\}$.

Let $\kappa(G)-1$ vertices from $S$ be deleted. Clearly the distance between any two vertices in $G$ is not affected by the removal of these vertices.
(b) Let $S$ be any arbitrary collection of vertices.

Consider a pair of diametral vertices $u_{x} v_{q}$ and $u_{y} v_{r}$ in $G$, then $d\left(u_{x} v_{q}, u_{y} v_{r}\right)=\operatorname{diam}\left(H_{1}\right)$ by a path $u_{x} v_{q}-u_{x+1} v_{a}-u_{x+2} v_{b}-\ldots-$ $u_{y} v_{r}$, since we have already considered the case of the deletion of the vertices from $S$ of the form $u_{x} v_{p}$ where $x \in\left\{1,2, \ldots, n_{1}\right\}$, there exist at least one vertex (say) $u_{i} v_{j}$ for each $j \in\left\{1,2, \ldots, n_{2}\right\}$ and are adjacent to the vertices $u_{r} v_{p}$ where $p \in\left\{1,2,3, \ldots, n_{2}\right\}$. Thus, the diam(G) remains the same.

Now, consider a pair of vertices $u_{p} v_{w}$ and $u_{q} v_{w}$ in $G$. Let the vertices $u_{i} v_{p}$ where $\left\{u_{i}\right\}$ is a collection of $\kappa\left(H_{1}\right)$ vertices which form a vertex cut of $H_{1}$ and $p \in\left\{1,2, \ldots, n_{2}-1\right\}$, be deleted. From the $H_{1}$ - layer at $v_{n_{2}}$ in $G$, we delete only the $\kappa\left(H_{1}\right)-1$ vertices, otherwise $G$ becomes disconnected. Then, $d\left(u_{p} v_{n_{2}}, u_{q} v_{n_{2}}\right) \leqslant f\left(H_{1}\right)$ by a path $u_{p} v_{n_{2}}-u_{p+1} v_{n_{2}}-\ldots-$
$u_{q-1} v_{n_{2}}-u_{q} v_{n_{2}}$, since the deletion of $\kappa\left(H_{1}\right)-1$ vertices from $H_{1}$ increases the $\operatorname{diam}\left(H_{1}\right)$ to at most $f\left(H_{1}\right)$. Now,
$d\left(u_{p} v_{w}, u_{q} v_{w}\right) \leqslant f\left(H_{1}\right)$ by a path $u_{p} v_{w}-u_{p+1} v_{n_{2}}-\ldots-u_{q-1} v_{n_{2}}-$ $u_{q} v_{w}$. Thus, $f(G) \leqslant f\left(H_{1}\right)$.

From the above cases, the result follows.

## Illustration of Theorem 3.1.6

Fig 3.6: Graphs with $f(G)=f\left(H_{1}\right)$ and $f(G)=f\left(H_{2}\right)$.

Theorem 3.1.7. Let $G \cong H_{1} \boxtimes H_{2}$ be a connected graph. Then $f(G) \leqslant \max \left\{f\left(H_{1}\right)+\operatorname{diam}\left(H_{2}\right), f\left(H_{2}\right)+\operatorname{diam}\left(H_{1}\right)\right\}$.

Proof. Case 1: $H_{1} \boxtimes K_{n_{2}}$.

Then $\operatorname{diam}(\mathrm{G})=\operatorname{diam}\left(H_{1}\right)$ and $\kappa\left(H_{1} \boxtimes K_{n_{2}}\right)=n_{2} \kappa\left(H_{1}\right)$.
From the Case 2 and Case 3 of Theorem 3.1.6, it follows that $f(G) \leqslant f\left(H_{1}\right)$.

Case 2: $H_{1} \boxtimes H_{2}$ where $H_{1}$ and $H_{2}$ are not complete graphs.

Suppose that $\operatorname{diam}(\mathrm{G})=\operatorname{diam}\left(H_{1}\right)$. We shall prove the theorem by considering the following sub cases.
(a) Let $S$ be the set of vertices of the form $u_{i} v_{p}$ where $i \in\left\{1,2,3, \ldots, n_{1}\right\}$.

Consider a pair of vertices $u_{a} v_{q}$ and $u_{b} v_{q}$ in $G$. Let the $\kappa(G)-1$ vertices from $S$ be deleted. Then, $d\left(u_{a} v_{q}, u_{b} v_{q}\right) \leqslant \operatorname{diam}\left(H_{1}\right)$. Now, $d\left(u_{y} v_{a}, u_{y} v_{b}\right) \leqslant f\left(H_{2}\right)$, since the deletion of the vertex $v_{p}$ from $H_{2}$ increases the $\operatorname{diam}\left(H_{2}\right)$ to at most $f\left(H_{2}\right)$. Hence, $f(G) \leqslant \max \left\{\operatorname{diam}\left(H_{1}\right), f\left(H_{2}\right)\right\}$.
(b) Let $S$ be the set of vertices of the form $u_{j} v_{p}$ where $p \in\left\{1,2,3, \ldots, n_{2}\right\}$.

Consider a pair of vertices $u_{w} v_{q}$ and $u_{w} v_{r}$ in $G$. Let the $\kappa(G)-1$ vertices from $S$ be deleted. Then, $d\left(u_{w} v_{q}, u_{w} v_{r}\right) \leqslant \operatorname{diam}\left(H_{2}\right)$. Now, $d\left(u_{a} v_{w}, u_{b} v_{w}\right) \leqslant f\left(H_{1}\right)$, since the deletion of the vertex $u_{x}$ from $H_{1}$ increases the $\operatorname{diam}\left(H_{1}\right)$ to at most $f\left(H_{1}\right)$. Hence, $f(G) \leqslant f\left(H_{1}\right)$.
(c) Let $S$ be any arbitrary collection of vertices.

Now, consider a pair of vertices $u_{p} v_{w}$ and $u_{q} v_{w}$ in $G$. Let the vertices $u_{i} v_{p}$ where $\left\{u_{i}\right\}$ is a collection of $\kappa\left(H_{1}\right)$ vertices which form a vertex cut of $H_{1}$ and $p \in\left\{1,2, \ldots, n_{2}-1\right\}$, be deleted. From the $H_{1}$ - layer at $v_{n_{2}}$ in $G$, we delete only the $\kappa\left(H_{1}\right)-1$ vertices, otherwise $G$ becomes disconnected. Then, $d\left(u_{p} v_{n_{2}}, u_{q} v_{n_{2}}\right) \leqslant f\left(H_{1}\right)$ by a path $u_{p} v_{n_{2}}-u_{p+1} v_{n_{2}}-\ldots-$ $u_{q-1} v_{n_{2}}-u_{q} v_{n_{2}}$, since the deletion of $\kappa\left(H_{1}\right)-1$ vertices from $H_{1}$ increases the $\operatorname{diam}\left(H_{1}\right)$ to at most $f\left(H_{1}\right)$. Now, $d\left(u_{p} v_{w}, u_{q} v_{w}\right) \leqslant f\left(H_{1}\right)+\operatorname{diam}\left(H_{2}\right)$, by a path $u_{p} v_{w}-u_{p} v_{w+1}-$ $\ldots-u_{p} v_{n_{2}}-\ldots-u_{q-1} v_{r}-u_{q} v_{w}$ where $d\left(u_{p} v_{w}, u_{p} v_{n_{2}}\right) \leqslant \operatorname{diam}\left(H_{2}\right)$ and $d\left(u_{p} v_{n_{2}}, u_{q} v_{w}\right) \leqslant f\left(H_{1}\right)$. Hence, the deletion of $\kappa(G)-1$ vertices increases the $\operatorname{diam}(\mathrm{G})$ to at most $f\left(H_{1}\right)+\operatorname{diam}\left(H_{2}\right)$.

Similarly, if $\operatorname{diam}(\mathrm{G})=\operatorname{diam}\left(H_{2}\right)$, then the deletion of $\kappa(G)-1$ vertices increases the $\operatorname{diam}(\mathrm{G})$ by $f\left(H_{2}\right)+\operatorname{diam}\left(H_{1}\right)$.

### 3.2 Diameter vulnerability of some graph classes

We shall first discuss the diameter vulnerability in grids.

Theorem 3.2.1. Let $G \cong P_{2} \square P_{n_{2}}$ be a grid, where $n_{2} \geqslant 2$. Then $f^{\prime}(G)=\operatorname{diam}(G)+1$.

Proof. Let $G \cong P_{2} \square P_{n_{2}}$. Then $\operatorname{diam}(\mathrm{G})=n_{2}$ and $\kappa^{\prime}(G)=2$.

Let $n_{2}>2$.
Let an edge $u_{1} v_{p}-u_{2} v_{p}$ where $p \in\left\{1,2, \ldots n_{2}\right\}$, be deleted. Then $d\left(u_{1} v_{p}, u_{2} v_{p}\right)=3 \leqslant n_{2}$ by a path $u_{1} v_{p}-u_{1} v_{q}-u_{2} v_{q}-u_{2} v_{p}$. Also, the distance between any two other vertices is not affected by the removal of this edge. Thus, the deletion of an edge does not increase the diam(G).

Consider a pair of vertices $u_{1} v_{1}, u_{1} v_{n_{2}}$ in $G$. Let an edge $u_{1} v_{p}-u_{1} v_{q}$, be deleted. There exist a unique path of length $n_{2}-1$ between them in $G$. Thus, $d\left(u_{1} v_{1}, u_{1} v_{n_{2}}\right)=n_{2}+1$ by a path $u_{1} v_{1}-u_{2} v_{1}-u_{2} v_{2}-\ldots-u_{2} v_{n_{2}}-u_{1} v_{n_{2}}$ where $d\left(u_{1} v_{1}, u_{2} v_{1}\right)=1, d\left(u_{2} v_{1}, u_{2} v_{n_{2}}\right)=n_{2}-1, d\left(u_{2} v_{n_{2}}, u_{1} v_{n_{2}}\right)=1$. Also, $d\left(u_{1} v_{p}, u_{1} v_{q}\right)=3$ and the distance between any two other vertices is not affected by the removal of this edge. Thus, the deletion of an edge increases the diam $(G)$ by one.

Let $n_{2}=2$. Then, $G$ is $C_{4}$ and $f^{\prime}(G)=3$.
Hence, $f^{\prime}(G)=\operatorname{diam}(G)+1$.

Note: For $n_{2}>2$, the deletion of a single edge will not change the diameter of $G$. In this context we consider $g^{\prime}(G)$ [69]. Consider a connected graph $G$ from which if $\kappa^{\prime}(G)$ edges are deleted, then the resulting graph $G$ (also denoted by $G$ ) is still connected. Then, $g^{\prime}(G)$ denotes the maximum diameter of a connected graph $G$ obtained when $\kappa^{\prime}(G)$ edges are deleted from $G$.

Theorem 3.2.2. Let $G \cong P_{3} \square P_{n_{2}}$ be a grid, where $n_{2} \geqslant 2$. Then $g^{\prime}(G)=\operatorname{diam}(G)+2$.

Proof. Let $G \cong P_{3} \square P_{n_{2}}$. Then $\operatorname{diam}(\mathrm{G})=n_{2}+1$ and $\kappa^{\prime}(G)=2$.

If any two edges are deleted arbitrarily, then the diam(G) remains the same, since there is a path of length three between them in $G$.

Consider a pair of diametral vertices $u_{1} v_{1}, u_{3} v_{n_{2}}$ in $G$. Let the edges $u_{3} v_{n_{2}-1}-u_{3} v_{n_{2}-2}$ and $u_{3} v_{n_{2}-1}-u_{2} v_{n_{2}-1}$, be deleted. Then, $d\left(u_{1} v_{1}, u_{3} v_{n_{2}-1}\right)=\operatorname{diam}(G)+1$ by a path $u_{1} v_{1}-u_{1} v_{2} \ldots u_{1} v_{n_{2}}-$ $u_{2} v_{n_{2}}-u_{3} v_{n_{2}}-u_{3} v_{n_{2}-1}$ where $d\left(u_{1} v_{1}, u_{1} v_{n_{2}}\right)=n_{2}-1$ and $d\left(u_{1} v_{n_{2}}, u_{3} v_{n_{2}-1}\right)=3$. Also, $d\left(u_{3} v_{n_{2}-1}, u_{2} v_{n_{2}-1}\right)=3$ and
$d\left(u_{3} v_{n_{2}-1}, u_{2} v_{n_{2}-2}\right)=5$. Thus, the deletion of two edges increases the $\operatorname{diam}(G)$ by one.

Consider a pair of vertices $u_{j} v_{1}, u_{j} v_{n_{2}}$ in $G$. Let the two edges $u_{i} v_{p}-u_{i} v_{q}$ and $u_{j} v_{p}-u_{j} v_{q}$ where $u_{i}$ is adjacent to $u_{j}$ in $P_{3}, j=1$ or 3 , be deleted. Then, $d\left(u_{j} v_{1}, u_{j} v_{n_{2}}\right)=n_{2}+3$ by a path $u_{j} v_{1}-u_{i} v_{1}-u_{x} v_{1}-u_{x} v_{2} \ldots u_{x} v_{n_{2}}-u_{i} v_{n_{2}}-u_{j} v_{n_{2}}$ where $d\left(u_{j} v_{1}, u_{x} v_{1}\right)=2, d\left(u_{x} v_{1}, u_{x} v_{n_{2}}\right)=n_{2}-1, d\left(u_{x} v_{n_{2}}, u_{j} v_{n_{2}}\right)=2$. Also, $d\left(u_{i} v_{p}, u_{i} v_{q}\right)=3$ and $d\left(u_{j} v_{p}, u_{j} v_{q}\right)=5$ by a path $u_{j} v_{p}-$ $u_{i} v_{p}-u_{x} v_{p}-u_{x} v_{q}-u_{i} v_{q}-u_{j} v_{q}$. Similarly, $d\left(u_{i} v_{1}, u_{i} v_{n_{2}}\right) \leqslant n_{2}+1$. Thus, the $\operatorname{diam}(G)$ increases by two.

Hence, $g^{\prime}(G)=\operatorname{diam}(G)+2$.

Theorem 3.2.3. Let $G \cong P_{n_{1}} \square P_{n_{2}}$ be a grid, where $n_{1}, n_{2} \geqslant 4$. Then $g^{\prime}(G)=\operatorname{diam}(G)+1$.

Proof. Let $G \cong P_{n_{1}} \square P_{n_{2}}$. Then $\operatorname{diam}(\mathrm{G})=n_{1}+n_{2}-2$ and $\kappa^{\prime}(G)=2$.

If any two edges are deleted arbitrarily, then the diam(G) remains the same, since there is a path of length three between them in $G$.

Let $n_{1}>4$.
Consider the vertices $u_{j} v_{1}, u_{j} v_{n}$ in $G$. Let the two edges $u_{i} v_{p}-$ $u_{i} v_{q}$ and $u_{j} v_{p}-u_{j} v_{q}$ where $u_{j}$ is adjacent to $u_{i}$ in $P_{n_{1}}$ and $i \neq 1$, $j \neq n_{1}$, be deleted. Then, $d\left(u_{i} v_{p}, u_{i} v_{q}\right)=3$ and $d\left(u_{j} v_{p}, u_{j} v_{q}\right)=3$. If $u_{j}$ is adjacent to $u_{i}$ in $P_{n_{1}}$ and $j=1$ or $n_{1}$, then $d\left(u_{i} v_{p}, u_{i} v_{q}\right)=3$ and $d\left(u_{j} v_{p}, u_{j} v_{q}\right)=5$ by a path $u_{j} v_{p}-u_{i} v_{p}-u_{x} v_{p}-u_{x} v_{q}-$ $u_{i} v_{q}-u_{j} v_{q}$. Also, $d\left(u_{j} v_{1}, u_{j} v_{n_{2}}\right)=\left(n_{2}-1\right)+4$ by a path $u_{j} v_{1}-u_{i} v_{1}-u_{x} v_{1}-u_{x} v_{2}-\ldots-u_{x} v_{n_{2}}-u_{i} v_{n_{2}}-u_{j} v_{n_{2}}$ where $d\left(u_{j} v_{n_{2}}, u_{x} v_{n_{2}}\right)=d\left(u_{x} v_{1}, u_{j} v_{1}\right)=2, d\left(u_{x} v_{1}, u_{x} v_{n_{2}}\right)=n_{2}-1$ and $d\left(u_{i} v_{1}, u_{i} v_{n_{2}}\right) \leqslant\left(n_{2}-1\right)+2$.

Similarly, if the two edges $u_{i} v_{p}-u_{j} v_{p}$ and $u_{i} v_{q}-u_{j} v_{q}$, are deleted then the diam(G) remains the same.

Let $n_{1}=4$.
Consider the vertices $u_{j} v_{1}, u_{j} v_{n_{2}}$ in $G$. Let the two edges $u_{i} v_{p}-$ $u_{i} v_{q}$ and $u_{j} v_{p}-u_{j} v_{q}$ where $u_{j}$ is adjacent to $u_{i}$ in $P_{n_{1}}$ and $i \neq 1$, $j \neq n_{1}$, be deleted. Then, $d\left(u_{i} v_{p}, u_{i} v_{q}\right)=3$ and $d\left(u_{j} v_{p}, u_{j} v_{q}\right)=3$. If $u_{j}$ is adjacent to $u_{i}$ in $P_{n_{1}}$ and $j=1$ or $n_{1}$, then the $\operatorname{diam}(\mathrm{G})$ increases by one. Also, $d\left(u_{j} v_{1}, u_{j} v_{n_{2}}\right)=n_{2}+3$ by a path $u_{j} v_{1}-u_{i} v_{1}-u_{x} v_{1}-u_{x} v_{2}-\ldots-u_{x} v_{n_{2}}-u_{i} v_{n_{2}}-u_{j} v_{n_{2}}$ where $d\left(u_{j} v_{n_{2}}, u_{x} v_{n_{2}}\right)=d\left(u_{x} v_{1}, u_{j} v_{1}\right)=2$ and $d\left(u_{x} v_{1}, u_{x} v_{n_{2}}\right)=n_{2}-1$.

Consider a pair of diametral vertices $u_{1} v_{1}, u_{n_{1}} v_{n_{2}}$ in $G$. Let the edges $u_{n_{1}} v_{n_{2}-1}-u_{n_{1}} v_{n_{2}-2}, u_{n_{1}} v_{n_{2}-1}-u_{n_{1}-1} v_{n_{2}-1}$, be deleted. Then, $d\left(u_{1} v_{1}, u_{n_{1}} v_{n_{2}-1}\right)=\operatorname{diam}(\mathrm{G})+1$ by a path $u_{1} v_{1}-u_{1} v_{2}-$ $\ldots u_{1} v_{n_{2}-1}-u_{1} v_{n_{2}}-u_{2} v_{n_{2}}-\ldots-u_{n_{1}-1} v_{n_{2}}-u_{n_{1}} v_{n_{2}}-u_{n_{1}} v_{n_{2}-1}$
where $d\left(u_{1} v_{1}, u_{1} v_{n_{2}}\right)=n_{2}-1$ and $d\left(u_{1} v_{n_{2}}, u_{n_{1}} v_{n_{2}-1}\right)=n_{1}$.
Also, $d\left(u_{n_{1}} v_{n_{2}-1}, u_{n_{1}-1} v_{n_{2}-1}\right)=3, d\left(u_{n_{1}} v_{n_{2}-1}, u_{n_{1}} v_{n_{2}-2}\right)=5$. Thus, the deletion of two edges increases the $\operatorname{diam}(G)$ by one.

Hence, $g^{\prime}(G)=\operatorname{diam}(G)+1$.

We shall now consider the case of cylinders.

Theorem 3.2.4. Let $G \cong P_{n_{1}} \square C_{n_{2}}$ be a cylinder where $n_{1}, n_{2} \geqslant 4$.
Then $f^{\prime}(G)=\operatorname{diam}(G)+1$ and $g^{\prime}(G)=\operatorname{diam}(G)+2$.

Proof. Let $G \cong P_{n_{1}} \square C_{n_{2}}$. Then $\kappa^{\prime}(G)=3$ and $\operatorname{diam}(\mathrm{G})=n_{1}-1+\left\lfloor n_{2} / 2\right\rfloor$. Let $d\left(v_{w}, v_{z}\right)=\operatorname{diam}\left(C_{n_{2}}\right)$.

If any two edges are deleted arbitrarily, then the diam(G) remains the same, since there is a path of length three between them in $G$.

Consider the vertices $u_{j} v_{w}, u_{j} v_{z}$ in $G$. Let the edges $u_{i} v_{p}-$ $u_{i} v_{q}, u_{j} v_{p}-u_{j} v_{q}$ where $u_{j}$ is adjacent to $u_{i}$ in $P_{n_{1}}$ and $i, j \neq 1, n_{1}$,
be deleted. Then, $d\left(u_{i} v_{p}, u_{i} v_{q}\right)=3$ and $d\left(u_{j} v_{p}, u_{j} v_{q}\right)=3$. If $u_{j}$ is adjacent to $u_{i}$ in $P_{n_{1}}$ and $j=1$ or $n_{1}$, then the $\operatorname{diam}(\mathrm{G})$ remains the same, since $d\left(u_{i} v_{p}, u_{i} v_{q}\right)=3, d\left(u_{i} v_{p}, u_{j} v_{q}\right)=d\left(u_{i} v_{q}, u_{j} v_{p}\right)=4$ and $d\left(u_{j} v_{p}, u_{j} v_{q}\right)=5$ by a path $u_{j} v_{p}-u_{i} v_{p}-u_{x} v_{p}-u_{x} v_{q}-u_{i} v_{q}-$ $u_{j} v_{q}$. Also, $d\left(u_{j} v_{w}, u_{j} v_{z}\right) \leqslant\left\lfloor n_{2} / 2\right\rfloor+4$ by a path $u_{j} v_{w}-u_{i} v_{w}-$ $u_{x} v_{w}-u_{x} v_{w+1} \ldots u_{x} v_{z}-u_{i} v_{z}-u_{j} v_{z}$ where $d\left(u_{j} v_{w}, u_{x} v_{w}\right)=2$, $d\left(u_{x} v_{w}, u_{j} v_{z}\right)=\left\lfloor n_{2} / 2\right\rfloor+2$. Thus, the diam(G) remains the same.

Consider a pair of vertices $u_{1} v_{1}, u_{n_{1}} v_{\left\lfloor n_{2} / 2\right\rfloor+1}$ in $G$. Let the edges $u_{n_{1}} v_{\left\lfloor n_{2} / 2\right\rfloor}-u_{n_{1}} v_{\left\lfloor n_{2} / 2\right\rfloor-1}, u_{n_{1}} v_{\left\lfloor n_{2} / 2\right\rfloor}-u_{n_{1}-1} v_{\left\lfloor n_{2} / 2\right\rfloor}$, be deleted. Then, $d\left(u_{1} v_{1}, u_{n_{1}} v_{\left\lfloor n_{2} / 2\right\rfloor}\right)=\operatorname{diam}(G)+1$ by a path $u_{1} v_{1}-u_{1} v_{2}-$ $\ldots-u_{1} v_{\left\lfloor n_{2} / 2\right\rfloor+1}-u_{2} v_{\left\lfloor n_{2} / 2\right\rfloor+1}-\ldots-u_{n_{1}} v_{\left\lfloor n_{2} / 2\right\rfloor+1}-u_{n_{1}} v_{\left\lfloor n_{2} / 2\right\rfloor}$ where $d\left(u_{1} v_{1}, u_{1} v_{\left\lfloor n_{2} / 2\right\rfloor+1}\right)=\left\lfloor n_{2} / 2\right\rfloor$ and $d\left(u_{1} v_{\left\lfloor n_{2} / 2\right\rfloor+1}, u_{n_{1}} v_{\left\lfloor n_{2} / 2\right\rfloor}\right)=n_{1}$. Also, $d\left(u_{n_{1}} v_{\left\lfloor n_{2} / 2\right\rfloor}, u_{n_{1}-1} v_{\left\lfloor n_{2} / 2\right\rfloor}\right)=3, d\left(u_{n_{1}} v_{\left\lfloor n_{2} / 2\right\rfloor}, u_{n_{1}} v_{\left\lfloor n_{2} / 2\right\rfloor+1}\right)=5$.
Thus, the deletion of two edges increases the $\operatorname{diam}(G)$ by one [see Fig 3.7].

Hence, $f^{\prime}(G)=\operatorname{diam}(G)+1$.

Now, we shall prove that $g^{\prime}(G)=\operatorname{diam}(G)+2$. Consider a pair of vertices $u_{1} v_{1}, u_{n_{1}} v_{\left\lfloor n_{2} / 2\right\rfloor+1}$ in $G$. Let the three edges $u_{n_{1}} v_{\left\lfloor n_{2} / 2\right\rfloor-1}-u_{n_{1}} v_{\left\lfloor n_{2} / 2\right\rfloor-2}, u_{n_{1}} v_{\left\lfloor n_{2} / 2\right\rfloor-1}-u_{n_{1}-1} v_{\left\lfloor n_{2} / 2\right\rfloor-1}$,

## 114 Chapter 3. Diameter vulnerability of the product graphs

Fig 3.7: A graph $G \cong P_{n_{1}} \square C_{n_{2}}$ with $f^{\prime}(G)=\operatorname{diam}(G)+1$.
and $u_{n_{1}} v_{\left\lfloor n_{2} / 2\right\rfloor}-u_{n_{1}-1} v_{\left\lfloor n_{2} / 2\right\rfloor}$, be deleted. Then, $d\left(u_{1} v_{1}, u_{n_{1}} v_{\left\lfloor n_{2} / 2\right\rfloor-1}\right)$ $=\operatorname{daim}(G)+2$ by a path $u_{1} v_{1}-u_{1} v_{2}-\ldots-u_{1} v_{\left\lfloor n_{2} / 2\right\rfloor+1}-$ $u_{2} v_{\left\lfloor n_{2} / 2\right\rfloor+1}-\ldots-u_{n_{1}} v_{\left\lfloor n_{2} / 2\right\rfloor+1}-u_{n_{1}} v_{\left\lfloor\left(n_{2} / 2\right)\right\rfloor}-u_{n_{1}} v_{\left\lfloor\left(n_{2} / 2\right)\right\rfloor-1}$. Also, $d\left(u_{n_{1}} v_{\left\lfloor n_{2} / 2\right\rfloor}, u_{n_{1}-1} v_{\left\lfloor n_{2} / 2\right\rfloor}\right)=3, d\left(u_{n_{1}} v_{\left\lfloor n_{2} / 2\right\rfloor-1}, u_{n_{1}} v_{\left\lfloor n_{2} / 2\right\rfloor-2}\right)=7$, $d\left(u_{n_{1}} v_{\left\lfloor n_{2} / 2\right\rfloor-1}, u_{n_{1}-1} v_{\left\lfloor n_{2} / 2\right\rfloor-1}\right)=5$. Thus, the deletion of three edges increases the diam(G) by two [see Fig 3.8].

Hence, $g^{\prime}(G)=\operatorname{diam}(G)+2$.

Fig 3.8: A graph $G \cong P_{n_{1}} \square C_{n_{2}}$ with $g^{\prime}(G)=\operatorname{diam}(G)+2$.

Finally, we consider the case of tori.
Let $G \cong C_{n_{1}} \square C_{n_{2}}$. For $n_{1}, n_{2} \leqslant 5$, we observe that $f^{\prime}(G)$ and $g^{\prime}(G)$ are either $\operatorname{diam}(G)+1$ or $\operatorname{diam}(G)+2$. Hence, we consider $n_{1}, n_{2} \geqslant 6$ and show that $f^{\prime}(G)=\operatorname{diam}(G)+1$ and $g^{\prime}(G)=\operatorname{diam}(\mathrm{G})+2$.

Fig 3.9: Graphs $G_{1}$ with $f^{\prime}\left(G_{1}\right)=\operatorname{diam}\left(G_{1}\right)+1$ and $G_{2}$ with $f^{\prime}\left(G_{2}\right)=\operatorname{diam}\left(G_{2}\right)+2$.

Fig 3.10: Graphs $G_{1}$ with $g^{\prime}\left(G_{1}\right)=\operatorname{diam}\left(G_{1}\right)+1$ and $G_{2}$ with $g^{\prime}\left(G_{2}\right)=\operatorname{diam}\left(G_{2}\right)+2$.

Theorem 3.2.5. Let $G \cong C_{n_{1}} \square C_{n_{2}}$ be a tori, where $n_{1}, n_{2} \geqslant 6$, then $f^{\prime}(G)=\operatorname{diam}(G)+1$. Further, $g^{\prime}(G)=\operatorname{diam}(G)+2$ where $n_{1}$ and $n_{2}$ are odd with $n_{1}, n_{2} \geqslant 6$.

Proof. Let $G \cong C_{n_{1}} \square C_{n_{2}}$. Then $\kappa^{\prime}(G)=4$ and $\operatorname{diam}(\mathrm{G})=\left\lfloor n_{1} / 2\right\rfloor+\left\lfloor n_{2} / 2\right\rfloor$.

If any two edges are deleted arbitrarily, then the diam(G) remains the same, since there is a path of length three between them in $G$.

Let the three edges $u_{i} v_{p}-u_{i} v_{q}, u_{j} v_{p}-u_{j} v_{q}$ and $u_{x} v_{p}-u_{x} v_{q}$ where $u_{j}$ is adjacent to $u_{i}$ and $u_{x}$ in $C_{n_{1}}$, be deleted. Then $d\left(u_{i} v_{p}, u_{i} v_{q}\right)=3=d\left(u_{x} v_{p}, u_{x} v_{q}\right), d\left(u_{j} v_{p}, u_{j} v_{q}\right)=5$. Also, $d\left(u_{j} v_{w}, u_{j} v_{z}\right)=\left\lfloor n_{2} / 2\right\rfloor+4, d\left(u_{i} v_{w}, u_{i} v_{z}\right)=\left\lfloor n_{2} / 2\right\rfloor+2$ and $d\left(u_{x} v_{w}, u_{x} v_{z}\right)=\left\lfloor n_{2} / 2\right\rfloor+2$. Thus, the diam $(\mathrm{G})$ remains the same.

Consider a pair of diametral vertices $u_{1} v_{1}, u_{\left\lfloor n_{1} / 2\right\rfloor+1} v_{\left\lfloor n_{2} / 2\right\rfloor+1}$ in $G$. Let the three edges $u_{\left\lfloor n_{1} / 2\right\rfloor+1} v_{\left\lfloor n_{2} / 2\right\rfloor}-u_{\left\lfloor n_{1} / 2\right\rfloor+1} v_{\left\lfloor n_{2} / 2\right\rfloor-1}$, $u_{\left\lfloor n_{1} / 2\right\rfloor+1} v_{\left\lfloor n_{2} / 2\right\rfloor}-u_{\left\lfloor n_{1} / 2\right\rfloor} v_{\left\lfloor n_{2} / 2\right\rfloor}$ and $u_{\left\lfloor n_{1} / 2\right\rfloor+1} v_{\left\lfloor n_{2} / 2\right\rfloor}-u_{\left\lfloor n_{1} / 2\right\rfloor+2} v_{\left\lfloor n_{2} / 2\right\rfloor}$, be deleted. Then, the distance between these pairs of vertices is three. Now, $d\left(u_{1} v_{1}, u_{\left\lfloor n_{1} / 2\right\rfloor+1} v_{\left\lfloor n_{2} / 2\right\rfloor}\right)=\operatorname{diam}(G)+1$ by a path $u_{1} v_{1}-u_{1} v_{2}-\ldots-u_{1} v_{\left\lfloor n_{2} / 2\right\rfloor+1}-u_{2} v_{\left\lfloor n_{2} / 2\right\rfloor+1}-\ldots-$ $u_{\left\lfloor n_{1} / 2\right\rfloor+1} v_{\left\lfloor n_{2} / 2\right\rfloor+1}-u_{\left\lfloor n_{1} / 2\right\rfloor+1} v_{\left\lfloor n_{2} / 2\right\rfloor}$. Thus, the deletion of three edges increases the diam $(\mathrm{G})$ by one.

Hence, $f^{\prime}(G)=\operatorname{daim}(G)+1$.

Now we shall prove that $g^{\prime}(G)=\operatorname{daim}(G)+2$.
Consider a pair of vertices $u_{1} v_{1}, u_{\left\lfloor n_{1} / 2\right\rfloor+1} v_{\left\lfloor n_{2} / 2\right\rfloor+1}$ in $G$. Let the edges $u_{1} v_{1}-u_{1} v_{2}, u_{\left\lfloor n_{1} / 2\right\rfloor+1} v_{\left\lfloor n_{2} / 2\right\rfloor}-u_{\left\lfloor n_{1} / 2\right\rfloor} v_{\left\lfloor n_{2} / 2\right\rfloor}$, $u_{\left\lfloor n_{1} / 2\right\rfloor+1} v_{\left\lfloor n_{2} / 2\right\rfloor}-u_{\left\lfloor n_{1} / 2\right\rfloor+2} v_{\left\lfloor n_{2} / 2\right\rfloor}, u_{\left\lfloor n_{1} / 2\right\rfloor+1} v_{\left\lfloor n_{2} / 2\right\rfloor}-u_{\left\lfloor n_{1} / 2\right\rfloor+1} v_{\left\lfloor n_{2} / 2\right\rfloor-1}$, be deleted. Then, $d\left(u_{1} v_{1}, u_{\left\lfloor n_{1} / 2\right\rfloor+1} v_{\left\lfloor n_{2} / 2\right\rfloor}\right)=\operatorname{diam}(G)+2$ by a path $u_{1} v_{1}-u_{n_{1}} v_{1}-\ldots-u_{n_{1}} v_{\left\lfloor n_{2} / 2\right\rfloor+1}-u_{n_{1}-1} v_{\left\lfloor n_{2} / 2\right\rfloor+1}-$ $\ldots-u_{\left\lfloor n_{1} / 2\right\rfloor+1} v_{\left\lfloor n_{2} / 2\right\rfloor+1}-u_{\left\lfloor n_{1} / 2\right\rfloor+1} v_{\left\lfloor n_{2} / 2\right\rfloor+1}-u_{\left\lfloor n_{1} / 2\right\rfloor+1} v_{\left\lfloor n_{2} / 2\right\rfloor}$ where $d\left(u_{1} v_{1}, u_{n_{1}} v_{\left\lfloor n_{2} / 2\right\rfloor+1}\right)=\left\lfloor n_{2} / 2\right\rfloor+1$ and $d\left(u_{n_{1}} v_{\left\lfloor n_{2} / 2\right\rfloor+1}, u_{\left\lfloor n_{1} / 2\right\rfloor+1} v_{\left\lfloor n_{2} / 2\right\rfloor}\right)=$ $\left\lfloor n_{1} / 2\right\rfloor+1$. Also, $d\left(u_{\left\lfloor n_{1} / 2\right\rfloor+1} v_{\left\lfloor n_{2} / 2\right\rfloor}, u_{\left\lfloor n_{1} / 2\right\rfloor+1} v_{\left\lfloor n_{2} / 2\right\rfloor-1}\right)=5$, $d\left(u_{\left\lfloor n_{1} / 2\right\rfloor+1} v_{\left\lfloor n_{2} / 2\right\rfloor}, u_{\left\lfloor n_{1} / 2\right\rfloor} v_{\left\lfloor n_{2} / 2\right\rfloor}\right)=3, d\left(u_{1} v_{1}, u_{1} v_{2}\right)=3$ and $d\left(u_{\left\lfloor n_{1} / 2\right\rfloor+1} v_{\left\lfloor n_{2} / 2\right\rfloor}, u_{\left\lfloor n_{1} / 2\right\rfloor+2} v_{\left\lfloor n_{2} / 2\right\rfloor}\right)=3$. Thus, the deletion of four edges increases the $\operatorname{diam}(\mathrm{G})$ by two.

Hence, $g^{\prime}(G)=\operatorname{daim}(G)+2$.

### 3.3 Wide Diameter of the lexicographic product of graphs

Lemma 3.3.1. Let $G \cong H_{1} \circ H_{2}$. If there exists a container of width $w$ in $H_{1}$ which is of length $l$ then there exists a container of width $\kappa\left(H_{1}\right) \times\left|V\left(H_{2}\right)\right|$ which will be of the same length $l$ in
$G$.

Proof. Case 1: Consider the vertices of the form $u_{i} v_{j}$ and $u_{k} v_{j}$ where $i \neq k$ and $i, k \in\left\{1,2, \ldots, n_{1}\right\}$.

Since there exists a container of length $l$ in $H_{1}$, there exists a container of length at most $l$ between $u_{i}$ and $u_{k}$. If $P_{1}=u_{i}-$ $u_{i+1}-u_{i+2}-\ldots-u_{k-1}-u_{k}$ is a path in the container $C_{w}\left(u_{i}, u_{k}\right)$ of $H_{1}$, then $u_{i} v_{j}-u_{i+1} v_{j}-u_{i+2} v_{j}-\ldots-u_{k-1} v_{j}-u_{k} v_{j}$ is the corresponding path connecting $u_{i} v_{j}$ and $u_{k} v_{j}$ in $G$. Also, by the structure of the lexicographic product, $u_{i} v_{j}-u_{i+1} v_{a}-u_{i+2} v_{a}-$ $\ldots-u_{k-1} v_{a}-u_{k} v_{j}$ are also paths connecting $u_{i} v_{j}$ and $u_{k} v_{j}$ where $a \neq j$ and $a \in\left\{1,2, \ldots, n_{2}\right\}$ in $G$. Thus, corresponding to the $w$ internally vertex disjoint paths in $C_{w}\left(u_{i}, u_{k}\right)$ of $H_{1}$, we have shown the existence of $w\left|V\left(H_{2}\right)\right|$ internally disjoint paths between $u_{i} v_{j}$ and $u_{k} v_{j}$ in $G$ which are of length at most $l$. Since the length of the container in $H_{1}$ is $l$, there exists a pair of vertices $u_{x}$ and $u_{y}$ in $H_{1}$ such that the path joining $u_{x}$ and $u_{y}$ is of length $l$. As proved above we can show that $C_{w}\left(u_{x} v_{j}, u_{y} v_{j}\right)$ in $G$ is of length $l$.

Case 2: Consider the vertices of the form $u_{i} v_{j}$ and $u_{i} v_{k}$
where $j \neq k$ and $j, k \in\left\{1,2, \ldots, n_{2}\right\}$.

By the structure of the lexicographic product, if $u_{i}$ is adjacent to $u_{a}$ in $H_{1}$, then both $u_{i} v_{j}$ and $u_{i} v_{k}$ will be adjacent to $u_{a} v_{1}, u_{a} v_{2}, \ldots, u_{a} v_{m}$ in $G$. Thus there exists at least $d_{G}\left(u_{i}\right)\left|V\left(H_{2}\right)\right|$ internally vertex disjoint paths between $u_{i} v_{j}$ and $u_{i} v_{k}$ which are of length two. So we can say that for any vertex $u_{i}$ in $H_{1}$, there exists $C_{\delta(G)\left|V\left(H_{2}\right)\right|}\left(u_{i} v_{j}, u_{i} v_{k}\right)$ of length two in $G$.

Case 3: Consider the vertices of the form $u_{i} v_{j}$ and $u_{a} v_{b}$ where $i \neq a$ and $j \neq b$.

Consider the vertices $u_{i}$ and $u_{a}$ in $H_{1}$. By the assumption there exists a container of length at most $l$ in between $u_{i}$ and $u_{a}$ in $H_{1}$. If $P_{1}=u_{i}-u_{i+1}-u_{i+2}-\ldots-u_{a-1}-u_{a}$ is a path in the container $C_{w}\left(u_{i}, u_{k}\right)$, then $u_{i} v_{j}-u_{i+1} v_{j}-u_{i+2} v_{j}-\ldots-$ $u_{a-1} v_{j}-u_{a} v_{b}$ is a path connecting $u_{i} v_{j}$ and $u_{a} v_{b}$ in $G$ which is of length same as that of $P_{1}$. Again, by the structure of the lexicographic product, we can find $w\left|V\left(H_{2}\right)\right|$ internally vertex disjoint paths between $u_{i} v_{j}$ and $u_{a} v_{b}$ and is of length at most $l$. Since the length of the container in $H_{1}$ is $l$, there exists a pair of vertices $u_{x}$ and $u_{y}$ in $H_{1}$ such that the path joining $u_{x}$ and $u_{y}$ is of length $l$. So $C_{w}\left(u_{x} v_{j}, u_{y} v_{b}\right)$ in $G$ is of length exactly $l$.

Finally, since $1 \leqslant w \leqslant \kappa(G)$ and $\kappa(G) \leqslant \delta(G)$, the result follows.

Theorem 3.3.2. For any two connected graphs $H_{1}$ and $H_{2}$, Wide diameter $\left(H_{1} \circ H_{2}\right)=$ Wide diameter $\left(H_{1}\right)$.

Proof. Suppose that $G \cong H_{1} \circ H_{2}$.
Let $D_{\kappa\left(H_{1}\right)}\left(H_{1}\right)=k$. Then there exists a container of width $\kappa\left(H_{1}\right)$ in between any two vertices of $H_{1}$ which is of length at most $k$. Then, by Lemma 3.3.1, there exists a container of width $\kappa\left(H_{1}\right) \times\left|V\left(H_{2}\right)\right|$ in between any two vertices of $G$ which is of length at most $k$.

Hence, $D_{\kappa\left(H_{1}\right) \times\left|V\left(H_{2}\right)\right|}\left(H_{1} \circ H_{2}\right) \leqslant D_{\kappa\left(H_{1}\right)}\left(H_{1}\right)$.

Let $D_{\kappa\left(H_{1}\right) \times\left|V\left(H_{2}\right)\right|}\left(H_{1} \circ H_{2}\right)=k$.
Consider any two vertices $u_{i}$ and $u_{j}$ in $H_{1}$. Clearly there exists $\kappa\left(H_{1}\right)$ internally disjoint paths joining $u_{i}$ and $u_{j}$ in $H_{1}$. Since $D_{\kappa\left(H_{1}\right) \times\left|V\left(H_{2}\right)\right|}\left(H_{1} \circ H_{2}\right)=k$, there exist a container of length at most $k$ joining $u_{i} v_{1}$ and $u_{j} v_{1}$. Thus there exist a container of width $\kappa\left(H_{1}\right)$ which is of length at most $k$ joining $u_{i}$ and $u_{j}$ in $G$. Hence, $D_{\kappa\left(H_{1}\right)}\left(H_{1}\right) \leqslant D_{\kappa\left(H_{1}\right) \times\left|V\left(H_{2}\right)\right|}\left(H_{1} \circ H_{2}\right)$.

## Chapter 4

## Component factors of the product graphs

In this chapter we study the component factors of the product graphs. We show that if $G \cong H_{1} * H_{2}$ where $* \in\{\square, \boxtimes, \circ\}$ and $H_{1}, H_{2}$ are connected graphs then $G$ has a $\left\{K_{1, n}, C_{4}\right\}$-factor where $n \leqslant t$ and $t$ is the maximum degree of an induced subgraph $K_{1, t}$ in $H_{1}$ or $H_{2}$. In this chapter, we denote $K_{2}$ by $K_{1,1}$ and $P_{3}$ by $K_{1,2}$ for uniformity in notations.

[^2]
### 4.1 Component factors of the Cartesian product of graphs

Theorem 4.1.1. Let $G \cong H_{1} \square H_{2}$ be a connected graph where $\left|H_{1}\right|=n_{1}$ and $\left|H_{2}\right|=n_{2}$. Then $G$ has a $C_{4}$-factor if and only if $G$ is any one of the following graphs where,
(I) $H_{1}$ or $H_{2}$ has a $C_{4}$-factor.
(II) both $H_{1}$ and $H_{2}$ have no $C_{4}$-factor and,
(a) both $H_{1}$ and $H_{2}$ are complete graphs with $n_{1}, n_{2}$ even and $n_{1}, n_{2} \not \equiv 0 \bmod 4$.
(b) $H_{1}$ is a complete graph with $n_{1}$ even and $H_{2}$ is a not complete graph with $n_{2}$ even, has at least one vertex with at most one pendant vertex attached to it and has a $\left\{K_{1,1}\right\}$-factor.
(c) $H_{1}$ and $H_{2}$ are not complete graphs with $n_{1}, n_{2}$ even, both have at least one vertex with at most one pendant vertex attached to it and have a $\left\{K_{1,1}\right\}$-factor.

Proof. Let $G \cong H_{1} \square H_{2}$ where $\left|H_{1}\right|=n_{1}$ and $\left|H_{2}\right|=n_{2}$.
(I) $H_{1}$ or $H_{2}$ has a $C_{4}$-factor.

Suppose that $H_{1}$ has a $C_{4}$-factor.

Consider the $H_{1}$ - layer at $v_{1}$ in $G$. Now, the vertices $u_{i} v_{1}$ where $i \in\left\{1,2,3, \ldots, n_{1}\right\}$ form a subgraph whose components are $C_{4}$, since $H_{1}$ has a $C_{4}$-factor. Similarly, the vertices $u_{i} v_{p}$ where $i \in\left\{1,2,3, \ldots, n_{1}\right\}$ and $p \in\left\{2,3, \ldots, n_{2}\right\}$ form a subgraph whose components are $C_{4}$. Hence, $G$ has a $C_{4}$-factor.
(II) Both $H_{1}$ and $H_{2}$ have no $C_{4}$-factor.
(a) Suppose that both $H_{1}$ and $H_{2}$ are complete graphs with $n_{1}, n_{2}$ even and $n_{1}, n_{2} \not \equiv 0 \bmod 4$.

Since both $H_{1}$ and $H_{2}$ are complete graphs with $n_{1}, n_{2}$ even, we can find a spanning subgraph of $H_{1}$ and $H_{2}$ whose components are $K_{1,1}$. Now, a $K_{1,1}$ from $H_{1}$ and a $K_{1,1}$ from $H_{2}$ form a $C_{4}$ in $G$. Thus, $G$ has a spanning subgraph $H$ whose components are $C_{4}$.
(b) Suppose that $H_{1}$ is a complete graph with $n_{1}$ even and $H_{2}$ is a not complete graph with $n_{2}$ even, has vertices with at most one pendant vertex attached to it and has a $\left\{K_{1,1}\right\}$-factor

There is a spanning subgraph of $H_{2}$ whose components are $K_{1,1}$. Also, $H_{1}$ has a $K_{1,1}$-factor. Hence, $G$ has a $C_{4}$-factor.
(c) From II(b), it follows that $G$ has a $C_{4}$-factor.

Conversely suppose that $G$ has a $C_{4}$-factor. Let $G \cong H_{1} \square H_{2}$. Suppose that both $n_{1}, n_{2}$ are odd. Then $H_{1}$ and $H_{2}$ cannot have a spanning subgraph whose components are $K_{1,1}$. Hence, $G$ has no $C_{4}$-factor. Thus, at least one graph should be of even order.
(i) $n_{1}$ even and $n_{2}$ odd.

If $H_{1}$ has no $C_{4}$-factor, then $G$ has no $C_{4}$-factor, since $n_{2}$ is odd. Hence, $H_{1}$ has a $C_{4}$-factor. This proves (I).

Similar is the case when $n_{1}$ is odd and $n_{2}$ is even.
(iii) Both $n_{1}, n_{2}$ are even.
(a) $G \cong K_{n_{1}} \square K_{n_{2}}$.

Clearly $G$ has a $C_{4}$-factor. This proves II(a).
(b) $G \cong K_{n_{1}} \square H_{2}$ where $H_{2}$ is a not complete graph.

If $H_{2}$ has a vertex $v_{x}$ with at least two pendant vertices $v_{i}, v_{j}$ attached to it, then in $G\left\langle u_{p} v_{x}, u_{p} v_{i}, u_{q} v_{i}, u_{q} v_{x}\right\rangle$ form a $C_{4}$ and $\left\langle u_{p} v_{j}, u_{q} v_{j}\right\rangle$ form an edge. Thus, $G$ has no $C_{4}$-factor. Hence, $H_{2}$ is a not complete graph with $n_{2}$ even and has vertices with at most one pendant vertex attached to it.

Now, we know that $H_{1}$ has a spanning subgraph whose components are $K_{1,1}$. Hence, $G$ has a $C_{4}$-factor only if $H_{2}$ has a $\left\{K_{1,1}\right\}$-factor This proves II(b).
(c) $G \cong H_{1} \square H_{2}$ where both $H_{1}$ and $H_{2}$ are not complete graphs.

If $H_{1}$ has a vertex $u_{p}$ with at least two pendant vertices $u_{a}, u_{b}$ attached to it and $H_{2}$ has a vertex $v_{x}$ with at least two pendant vertices $v_{i}, v_{j}$ attached to it, then in $G\left\langle u_{p} v_{r}, u_{p} v_{s}, u_{a} v_{s}, u_{a} v_{r}\right\rangle$ and $\left\langle u_{p} v_{x}, u_{p} v_{i}, u_{q} v_{i}, u_{q} v_{x}\right\rangle$ form $C_{4} \mathrm{~S}$ and $\left\langle u_{p} v_{r}, u_{b} v_{r}\right\rangle,\left\langle u_{p} v_{j}, u_{q} v_{j}\right\rangle$ form $K_{1,1}$ s. Thus, $G$ has no $C_{4}$-factor. Hence, both have at least one vertex with at most one pendant vertex attached to it.

Now, $G$ has a $C_{4}$-factor only if both $H_{1}$ and $H_{2}$ has a $\left\{K_{1,1}\right\}$ factor.

This proves II(c).

Theorem 4.1.2. Let $G \cong K_{n_{1}} \square K_{n_{2}}$ where $n_{1}, n_{2} \geqslant 2$. Then $G$ has a $\left\{K_{1,2}, C_{4}\right\}$-factor.

Proof. We shall prove the theorem by considering the fol-
lowing three cases.
(I) Both $n_{1}, n_{2}$ are even.

From Theorem 4.1.1, it follows that $G$ has a $C_{4}$-factor.
(II) Both $n_{1}, n_{2}$ are odd.
(a) Suppose that $n_{1} \equiv 0 \bmod 3$.

Since $n_{1} \equiv 0 \bmod 3$, we can find a spanning subgraph of $K_{n_{1}}$ whose components are $K_{1,2}$. Now, $G$ has a spanning subgraph $H$ whose components are $K_{1,2}$, since $K_{n_{1}}$ has a $K_{1,2}$-factor.
(b) Suppose that $n_{1}, n_{2} \equiv 1 \bmod 3$.

Since $n_{1} \equiv 1 \bmod 3$, we can find a spanning subgraph of $K_{n_{1}}$ whose components are $K_{1,2}$ and $K_{1,1}$ where $u_{1}, u_{2}, \ldots, u_{n_{1}-4}$ are the vertices in the components of $K_{1,2}$ and $u_{n_{1}-3}, u_{n_{1}-2}, u_{n_{1}-1}, u_{n_{1}}$ are the vertices in the components of $K_{1,1}$. Now, consider the vertices $u_{1} v_{p}, u_{2} v_{p}, \ldots, u_{n_{1}-4} v_{p}$ where $p \in\left\{1,2,3, \ldots, n_{2}\right\}$ in $G$, they form a subgraph whose components are $K_{1,2}$. The remaining vertices of $G, u_{n_{1}-3} v_{p}, u_{n_{1}-2} v_{p}, u_{n_{1}-1} v_{p}, u_{n_{1}} v_{p}$ where $p \in\left\{1,2,3, \ldots, n_{2}-4\right\}$ form a subgraph whose components are $K_{1,2}$ and $\left\langle u_{n_{1}-3} v_{n_{2}-3}, u_{n_{1}-3} v_{n_{2}-2}, u_{n_{1}-2} v_{n_{2}-2}, u_{n_{1}-2} v_{n_{2}-3}\right\rangle$, $\left\langle u_{n_{1}-3} v_{n_{2}-1}, u_{n_{1}-3} v_{n_{2}}, u_{n_{1}-2} v_{n_{2}}, u_{n_{1}-2} v_{n_{2}-1}\right\rangle$,
$\left\langle u_{n_{1}-1} v_{n_{2}-3}, u_{n_{1}-1} v_{n_{2}-2}, u_{n_{1}} v_{n_{2}-2}, u_{n_{1}} v_{n_{2}-3}\right\rangle$ and $\left\langle u_{n_{1}-1} v_{n_{2}-1}, u_{n_{1}-1} v_{n_{2}}, u_{n_{1}} v_{n_{2}}, u_{n_{1}} v_{n_{2}-1}\right\rangle$ form $C_{4} \mathrm{~S}$.
(c) Suppose that $n_{1}, n_{2} \equiv 2 \bmod 3$.

Since $n_{1} \equiv 2 \bmod 3$, we can find a spanning subgraph of $K_{n_{1}}$ whose components are $K_{1,2}$ and $K_{1,1}$ where $u_{1}, u_{2}, \ldots, u_{n_{1}-2}$ are the vertices in the components of $K_{1,2}$ and $u_{n_{1}-1}, u_{n_{1}}$ are the vertices in the components of $K_{1,1}$. Now, consider the vertices $u_{1} v_{p}, u_{2} v_{p}, \ldots, u_{n_{1}-2} v_{p}$ where $p \in\left\{1,2,3, \ldots, n_{2}\right\}$ in $G$, they form a subgraph whose components are $K_{1,2}$. The remaining vertices of $G, u_{n_{1}-1} v_{p}$ where $p \in\left\{1,2,3, \ldots, n_{2}-2\right\}$ and $u_{n_{1}} v_{p}$ where $p \in\left\{1,2,3, \ldots, n_{2}-2\right\}$ form a subgraph whose components are $K_{1,2}$ and $\left\langle u_{n_{1}-1} v_{n_{2}-1}, u_{n_{1}-1} v_{n_{2}}, u_{n_{1}} v_{n_{2}}, u_{n_{1}} v_{n_{2}-1}\right\rangle$ form a $C_{4}$.
(d) Suppose that $n_{1} \equiv 2 \bmod 3$ and $n_{2} \equiv 1 \bmod 3$.

Clearly $K_{n_{1}}$ and $K_{n_{2}}$ has a $\left\{K_{1,1}, K_{1,2}\right\}$-factor. Consider the vertices $u_{1} v_{p}, u_{2} v_{p}, \ldots, u_{n_{1}-2} v_{p}$ where $p \in\left\{1,2,3, \ldots, n_{2}\right\}$ in $G$, they form a subgraph whose components are $K_{1,2}$. The remaining vertices of $G, u_{n_{1}-1} v_{p}$ where $p \in\left\{1,2,3, \ldots, n_{2}-4\right\}$ and $u_{n_{1}} v_{p}$ where $p \in\left\{1,2,3, \ldots, n_{2}-4\right\}$ form a subgraph whose components are $K_{1,2}$ and $\left\langle u_{n_{1}-1} v_{n_{2}-3}, u_{n_{1}-1} v_{n_{2}-2}, u_{n_{1}} v_{n_{2}-2}, u_{n_{1}} v_{n_{2}-3}\right\rangle$,
$\left\langle u_{n_{1}-1} v_{n_{2}-1}, u_{n_{1}-1} v_{n_{2}}, u_{n_{1}} v_{n_{2}}, u_{n_{1}} v_{n_{2}-1}\right\rangle$ form $C_{4} \mathrm{~s}$.
(III) $n_{1}$ odd and $n_{2}$ even.
(a) Suppose that $n_{1} \equiv 0 \bmod 3$.

From II(a), it follows that $G$ has a $K_{1,2}$-factor.
(b) Suppose that $n_{1} \equiv 1 \bmod 3$.

Clearly $K_{n_{1}}$ has a $\left\{K_{1,1}, K_{1,2}\right\}$-factor and $K_{n_{2}}$ has a $K_{1,1^{-}}$ factor. Consider the vertices $u_{1} v_{p}, u_{2} v_{p}, \ldots, u_{n_{1}-4} v_{p}$ where $p \in\left\{1,2,3, \ldots, n_{2}\right\}$ in $G$, they form a subgraph whose components are $K_{1,2}$. Now, $\left\langle u_{n_{1}-3} v_{p}, u_{n_{1}-2} v_{p}, u_{n_{1}-2} v_{p+1}, u_{n_{1}-3} v_{p+1}\right\rangle$, $\left\langle u_{n_{1}-1} v_{p}, u_{n_{1}} v_{p}, u_{n_{1}} v_{p+1}, u_{n_{1}-1} v_{p+1}\right\rangle$ where $p \in\left\{1,2,3, \ldots, n_{2}-1\right\}$ form $C_{4}$ s.
(c) Suppose that $n_{1} \equiv 2 \bmod 3$.

Clearly $K_{n_{1}}$ has a $\left\{K_{1,1}, K_{1,2}\right\}$-factor and $K_{n_{2}}$ has a $K_{1,1^{-}}$ factor. Consider the vertices $u_{1} v_{p}, u_{2} v_{p}, \ldots, u_{n_{1}-2} v_{p}$ where $p \in\left\{1,2,3, \ldots, n_{2}\right\}$ in $G$, they form a subgraph whose components are $K_{1,2}$. Now, $\left\langle u_{n_{1}-1} v_{p}, u_{n_{1}} v_{p}, u_{n_{1}} v_{p+1}, u_{n_{1}-1} v_{p+1}\right\rangle$ where $p \in\left\{1,2,3, \ldots, n_{2}-1\right\}$ form $C_{4} \mathrm{~S}$.

Hence, $G$ has a $\left\{K_{1,2}, C_{4}\right\}$-factor.

Lemma 4.1.3. Let $G \cong K_{n_{1}} \square H_{2}$ be a connected graph where $n_{1} \geqslant 2$ and $H_{2}$ is any not complete graph. Then $G$ has a $\left\{K_{1,2}, C_{4}\right\}$-factor if $G$ is any one of the following graphs where, (a) either $K_{n_{1}}$ or $H_{2}$ has a $K_{1,2}$-factor or a $C_{4}$ - factor.
(b) both $n_{1}, n_{2}$ are even and $H_{2}$ has at least one vertex with at most one pendant vertex attached to it and has a $\left\{K_{1,1}\right\}$-factor. (c) $n_{1}$ even, $n_{2}$ odd and $H_{2}$ has at least one vertex with at most one pendant vertex attached to it and has a $\left\{K_{1,2}, K_{1,1}\right\}$-factor. (d) $n_{1}$ odd, $n_{2}$ even and $H_{2}$ has at least one vertex with at most one pendant vertex attached to it and has a $\left\{K_{1,1}\right\}$-factor.

Proof. (a) Suppose that $K_{n_{1}}$ or $H_{2}$ has a $C_{4}$-factor, then from Theorem 4.1.1 $G$ has a $C_{4}$-factor.

Suppose that $K_{n_{1}}$ or $H_{2}$ has a $K_{1,2}$-factor, then clearly $G$ has a $C_{4}$-factor.

Suppose that (b) holds, then from Theorem 4.1.1 $G$ has a $C_{4}$-factor.

Suppose that (c) holds.

Clearly, $H_{1}$ has a $K_{1,1}$-factor. We can find a spanning subgraph of $H_{2}$ whose components are $K_{1,2}$ and $K_{1,1}$ where $v_{1}, v_{2}, \ldots, v_{p}$ are the vertices in the components of $K_{1,2}$ and $v_{p+1}, v_{p+2}, \ldots, v_{n_{2}}$
are the vertices in the components of $K_{1,1}$. Consider the vertices $u_{x} v_{1}, u_{x} v_{2}, \ldots, u_{x} v_{p}$ where $x \in\left\{1,2,3, \ldots, n_{1}\right\}$ in $G$, they form a subgraph whose components are $K_{1,2}$. Now, $\left\langle u_{x} v_{p+1}, u_{x} v_{p+2}, u_{x+1} v_{p+1}, u_{x+1} v_{p+2}\right\rangle, \ldots$
$\left\langle u_{x} v_{n_{2}-1}, u_{x} v_{n_{2}}, u_{x+1} v_{n_{2}-1}, u_{x+1} v_{n_{2}}\right\rangle$ where $x \in\left\{1,2, \ldots, n_{1}-1\right\}$ form $C_{4}$ s.

Suppose that (d) holds.

If $n_{1} \equiv 0 \bmod 3$, then $K_{n_{1}}$ has a $K_{1,2}$-factor and hence the proof follows from Lemma 4.1.3(b).

If $n_{1} \equiv 1 \bmod 3$, then we can find a spanning subgraph of $K_{n_{1}}$ whose components are $K_{1,2}$ and $K_{1,1}$ where $u_{1}, u_{2}, \ldots, u_{n_{1}-4}$ are the vertices in the components of $K_{1,2}$ and $u_{n_{1}-3}, u_{n_{1}-2}, u_{n_{1}-1}, u_{n_{1}}$ are the vertices in the components of $K_{1,1}$. Consider the vertices $u_{1} v_{p}, u_{2} v_{p}, \ldots, u_{n_{1}-4} v_{p}$ where $p \in\left\{1,2,3, \ldots, n_{2}\right\}$, they form a subgraph whose components are $K_{1,2}$. Now, $\left\langle u_{n_{1}-3} v_{y}, u_{n_{1}-2} v_{y}, u_{n_{1}-2} v_{y+1}, u_{n_{1}-3} v_{y+1}\right\rangle$, $\left\langle u_{n_{1}-1} v_{y}, u_{n_{1}} v_{y}, u_{n_{1}} v_{y+1}, u_{n_{1}-1} v_{y+1}\right\rangle$ where $y \in\left\{1,2, \ldots, n_{2}-1\right\}$ form $C_{4}$ s.

If $n_{1} \equiv 2 \bmod 3$, then we can find a spanning subgraph of
$K_{n_{1}}$ whose components are $K_{1,2}$ and $K_{1,1}$ where $u_{1}, u_{2}, \ldots, u_{n_{1}-2}$ are the vertices in the components of $K_{1,2}$ and $u_{n_{1}-1}, u_{n_{1}}$ are the vertices in the components of $K_{1,1}$. Consider the vertices $u_{1} v_{p}, u_{2} v_{p}, \ldots, u_{n_{1}-2} v_{p}$ where $p \in\left\{1,2,3, \ldots, n_{2}\right\}$, they form a subgraph whose components are $K_{1,2}$. Now, $\left\langle u_{n_{1}-1} v_{y}, u_{n_{1}} v_{y}, u_{n} v_{y+1}, u_{n_{1}-1} v_{y+1}\right\rangle$ where $y \in\left\{1,2, \ldots, n_{2}-1\right\}$ form $C_{4} \mathrm{~s}$.

Hence, $G$ has a $\left\{K_{1,2}, C_{4}\right\}$-factor.

Lemma 4.1.4. Let $G \cong K_{n_{1}} \square H_{2}$ be a connected graph where $n_{1} \geqslant 2$ and $H_{2}$ is a not complete graph. Then $G$ has a $\left\{K_{1,1}, K_{1,2}\right\}$ factor if $G$ is any one of the following graphs where, (I) both $n_{1}, n_{2}$ are even and $H_{2}$ has either no pendant vertex or at least one vertex with at least one pendant vertex attached to $i t$.
(II) $n_{1}$ even, $n_{2}$ odd and $H_{2}$ has either no pendant vertex or at least one vertex with at least one pendant vertex attached to it. (III) $n_{1}$ odd, $n_{2}$ even and $H_{2}$ has either no pendant vertex or at least one vertex with at least one pendant vertex attached to it. (IV) both $n_{1}, n_{2}$ are odd.

Proof. If $n_{1} \equiv 0 \bmod 3$, then $K_{n_{1}}$ has a $K_{1,2}$-factor. If
$n_{1} \equiv 1 \bmod 3$ or $n_{1} \equiv 2 \bmod 3$, then $K_{n_{1}}$ has a $\left\{K_{1,1}, K_{1,2}\right\}$ factor. Hence, in all these cases $G$ has a $\left\{K_{1,1}, K_{1,2}\right\}$-factor.

Theorem 4.1.5. Let $G \cong K_{n_{1}} \square H_{2}$ be a connected graph where $H_{2}$ is a not complete graph. Then $G$ has a $\left\{K_{1,1}, K_{1,2}, C_{4}\right\}$ factor.

Proof. Follows from Lemma 4.1.3 and Lemma 4.1.4.

Lemma 4.1.6. Let $G \cong H_{1} \square H_{2}$ be a connected graph where $H_{1}$ and $H_{2}$ are not complete graphs. Then $G$ has a $\left\{K_{1,1}, K_{1,2}, C_{4}\right\}$ factor if $G$ is any one of the following graphs where, (I) either $H_{1}$ or $H_{2}$ has a a $K_{1,1}$-factor or a $K_{1,2}$-factor or a $C_{4}$-factor.
(II) $H_{1}$ and $H_{2}$ have no $K_{1,2}$-factor and $C_{4}$-factor and
(a) both $n_{1}, n_{2}$ are even and $H_{1}, H_{2}$ have at least one vertex with at most one pendant vertex attached to it and have a $K_{1,1^{-}}$ factor.
(b) $H_{1}$ has at least one vertex with at least two pendant vertices attached to it and $H_{2}$ has at least one vertex with at most one pendant vertex attached to it with $n_{2}$ even and has a $K_{1,1}$-factor.

Proof. Suppose that (I) holds, then clearly $G$ has a $K_{1,2^{-}}$
factor or a $C_{4}$-factor.
Suppose that II(a) holds, then from Theorem 4.1.1 $G$ has a $C_{4^{-}}$ factor.

Suppose that II(b) holds.
Consider the vertices $u_{i} \mathrm{~s}, u_{j} \mathrm{~s}$ in $H_{1}$ where $i, j \in\left\{1,2, \ldots, n_{1}\right\}$ and $u_{j}$ s are the pendant vertices in $H_{1}$. We can find a spanning subgraph of $H_{1}$ whose components are $K_{1,2}, K_{1,1}$ and $K_{1}$ where $u_{i}$ S are the vertices in the components of $K_{1,2}, K_{1,1}$ and $u_{j} \mathrm{~S}$ are the vertices in the $K_{1}$. Then in $G$, the vertices $u_{i} v_{p}$ where $p \in\left\{1,2, \ldots, n_{2}\right\}$ form a subgraph whose components are $K_{1,2}$ and $K_{1,1}$. Now, $\left\langle u_{j} v_{p}, u_{j} v_{p+1}\right\rangle$ where $p \in\left\{1,2, \ldots, n_{2}-1\right\}$ form $K_{1,1}$ s. Hence, $G$ has a $\left\{K_{1,1}, K_{1,2}\right\}$-factor.

Lemma 4.1.7. Let $G \cong H_{1} \square H_{2}$ be a connected graph where $H_{1}$ and $H_{2}$ are not complete graphs and have at least one vertex with at least one pendant vertex attached to $i t$. Then $G$ has a $\left\{K_{1, n}\right\}$-factor where $n \leqslant t$ and $t$ is the maximum degree of an induced subgraph $K_{1, t}$ in $H_{1}$ or $H_{2}$.

Proof. If $H_{1}$ and $H_{2}$ have at least one vertex with at least one pendant vertices attached to it, then $H_{1}$ has a $\left\{K_{1, p}\right\}$-factor and $H_{2}$ has a $\left\{K_{1, q}\right\}$-factor where $p, q \leqslant t$ and $t$ is the maximum
degree of an induced sub graph $K_{1, t}$ in $H_{1}$ or $H_{2}$. Hence, $G$ has a $\left\{K_{1, n}\right\}$-factor where $n \leqslant t$ and $t$ is the maximum degree of an induced subgraph $K_{1, t}$ in $H_{1}$ or $H_{2}$.

Theorem 4.1.8. Let $G \cong H_{1} \square H_{2}$ be a connected graph where $H_{1}$ and $H_{2}$ are not complete graphs. Then $G$ has a $\left\{K_{1, n}, C_{4}\right\}$ factor where $n \leqslant t$ and $t$ is the maximum degree of an induced subgraph $K_{1, t}$ in $H_{1}$ or $H_{2}$.

Proof. Follows from Lemma 4.1.6 and Lemma 4.1.7.

Theorem 4.1.9. Let $G \cong H_{1} * H_{2}$ where $* \in\{\square, \boxtimes, \circ\}$ and $H_{1}$, $H_{2}$ are connected graphs. Then $G$ has a $\left\{K_{1, n}, C_{4}\right\}$-factor where $n \leqslant t$ and $t$ is the maximum degree of an induced subgraph $K_{1, t}$ in $H_{1}$ or $H_{2}$.

Proof. Follows from Theorem 4.1.2, 4.1.5, 4.1.8 and the fact that the Cartesian product of two connected graphs is a spanning subgraph of the strong product and the lexicographic product of graphs.

### 4.2 Path factors of Hypercubes and Hamming graphs

Theorem 4.2.1. The hypercube $Q_{n}$ has a $\left\{P_{4}\right\}$-factor.

Proof. We prove the theorem by induction.
Let $n=2$.
Then $Q_{2}$ is $C_{4}$ and it has a path of length four.
Let $n=3$.
Then $Q_{3}$ has a $\left\{P_{4}\right\}$-factor as shown in Fig 4.1.

Fig 4.1: The graphs $Q_{2}, Q_{3}$ with a $P_{4}$-factor.

Assume that for $n=k, Q_{k}$ has a $\left\{P_{4}\right\}$-factor.
Next, we have to prove that $Q_{k+1}$ has a $\left\{P_{4}\right\}$-factor. We have $Q_{k+1} \cong Q_{k} \square K_{2}$. Now, in $G$ the vertices $u_{1} v_{1}, u_{1} v_{2}, \ldots, u_{1} v_{2^{k}}$ form $P_{4} \mathrm{~s}$, since $Q_{k}$ has a $\left\{P_{4}\right\}$-factor. Similarly, $u_{2} v_{1}, u_{2} v_{2}, \ldots, u_{2} v_{2^{k}}$ form $P_{4}$ s. Hence, $Q_{k+1}$ has a $P_{4}$-factor.

Theorem 4.2.2. A Hamming graph $G \cong K_{n_{1}} \square K_{n_{2}} \square K_{n_{3}} \square \ldots \square K_{n_{k}}$ has a $\left\{P_{3}, P_{4}\right\}$-factor.

Proof. Let $G \cong K_{n_{1}} \square K_{n_{2}} \square K_{n_{3}} \square \ldots \square K_{n_{k}}$.

Suppose that there exist one $n_{i}$ such that $n_{i} \leqslant n_{j}$ and $i \geqslant 3$. We know that the Cartesian product is associative. Hence, we consider $G$ as $G \cong\left(K_{n_{1}} \square K_{n_{2}} \square K_{n_{3}} \ldots \square K_{n_{k}}\right) \square K_{n_{i}}$. Let $H \cong\left(K_{n_{1}} \square K_{n_{2}} \square K_{n_{3}} \square \ldots \square K_{n_{k}}\right)$. Thus $G \cong H \square K_{n_{i}}$. Let $u_{j}$ and $v_{p}$ where $j \in\{1,2,3, \ldots,|H|\}$ and $p \in\left\{1,2,3, \ldots, n_{i}\right\}$ be the vertices of $H$ and $K_{n_{i}}$ respectively.

If $n_{i} \equiv 0 \bmod 3$, then $K_{n_{1}}$ has a $P_{3}$-factor. Consider $u_{j} v_{p^{-}}$ $u_{j} v_{q}$ where $j \in\{1,2,3, \ldots,|H|\}$ and $p, q \in\left\{1,2,3, \ldots, n_{i}\right\}$ in $G$. Since $n_{i} \equiv 0 \bmod 3, K_{n_{1}}$ has a $P_{3}$-factor and hence $G$ has a $P_{3}$-factor.

If $n_{i} \equiv 1 \bmod 3$, then we can find a spanning subgraph of $K_{n_{i}}$ whose components are $P_{3}$ and $P_{4}$ where $v_{1}, v_{2}, \ldots, v_{n_{i}-4}$ are the vertices in the components of $P_{3}$ and $v_{n_{i}-3}, v_{n_{i}-2}, v_{n_{i}-1}, v_{n_{i}}$ are the vertices in the components of $P_{4}$. Now, in $G$ the vertices $u_{1} v_{p}, u_{2} v_{p}, \ldots, u_{n_{i}-4} v_{p}$ where $p \in\{1,2,3, \ldots,|H|\}$ form a subgraph whose components are $P_{3}$. The $\left\langle u_{j} v_{n_{i}-3}, u_{j} v_{n_{i}-2}, u_{j} v_{n_{i}-1}, u_{j} v_{n_{i}}\right\rangle$
where $j \in\{1,2, \ldots,|H|\}$ form $P_{4}$ s. Thus, $G$ has a $\left\{P_{3}, P_{4}\right\}$ factor.

If $n_{i} \equiv 2 \bmod 3$, then we can find a spanning subgraph of $K_{n_{i}}$ whose components are $P_{3}$ and $P_{4}$ where $v_{1}, v_{2}, \ldots, v_{n_{i}-8}$ are the vertices in the components of $P_{3}$ and $v_{n_{i}-7}, v_{n_{i}-6}, \ldots, v_{n_{i}-1}, v_{n_{i}}$ are the vertices in the components of $P_{4}$. Now, in $G$ the vertices $u_{j} v_{1}, u_{j} v_{2}, \ldots, u_{j} v_{n_{i}-8}$ where $j \in\{1,2,3, \ldots,|H|\}$ form a subgraph whose components are $P_{3}$. The $\left\langle u_{j} v_{n_{i}-7}, u_{j} v_{n_{i}-6}, u_{j} v_{n_{i}-5}, u_{j} v_{n_{i}-4}\right\rangle$ and $\left\langle u_{j} v_{n_{i}-3}, u_{j} v_{n_{i}-2}, u_{j} v_{n_{i}-1}, u_{j} v_{n_{i}}\right\rangle$ where $j \in\{1,2,3, \ldots,|H|\}$ form $P_{4}$ s. Thus, $G$ has a $\left\{P_{3}, P_{4}\right\}$-factor.

## Chapter 5

## Domination criticality in the Cartesian product of graphs

A connected dominating set is an important notion and has many applications in routing and management of networks. In this chapter we study the Cartesian product of graphs $G$ with connected domination number, $\gamma_{c}(G)=2,3$ and characterize such graphs. Also, we characterize the $k-\gamma$ - vertex (edge) critical graphs and $k-\gamma_{c}$ - vertex (edge) critical graphs for $k=2$, 3 where $\gamma$ denotes the domination number of $G$. We also

[^3]Chapter 5. Domination criticality in the Cartesian product of 140 graphs
discuss the vertex criticality in grids.

### 5.1 Domination critical graphs

Theorem 5.1.1. Let $G \cong H_{1} \square H_{2}$ be a connected graph. Then $\gamma(G)=2$ if and only if $H_{1}=K_{2}$ and $H_{2}$ is either a $C_{4}$ or has a universal vertex.

Consider $G \cong K_{2} \square C_{4}$, then a minimum dominating set of $G$ is
$D=\left\{u_{1} v_{1}, u_{2} v_{3}\right\}$. If $G \cong K_{2} \square H_{2}$, where $H_{2}$ has a universal vertex $v_{i}$, then a minimum dominating set of $G$ is $D=\left\{u_{1} v_{i}, u_{2} v_{i}\right\}$. Hence, $\gamma(G)=2$ in both the cases.

Conversely suppose that $\gamma(G)=2$.

Suppose that both $H_{1}$ and $H_{2}$ are not complete graphs. Then, $\gamma(G) \geqslant \min \left\{\left|H_{1}\right|,\left|H_{2}\right|\right\} \geqslant 3$.

Hence, at least one graph (say) $H_{1}$ should be complete.

Let $G \cong K_{n_{1}} \square H_{2}$.
Suppose that $H_{1}$ is a complete graph of order at least three. If $H_{2}$ has a universal vertex, then a minimum dominating set of $G$ con-
tains vertices from each layer of $G$ and $3 \leqslant \gamma(G) \leqslant \min \left\{n_{1}, n_{2}\right\}$. If $H_{2}$ does not has a universal vertex, then $\gamma\left(H_{2}\right) \geqslant 2$ and a minimum dominating set of $G$ contains vertices from each layer of $G$ and $3 \leqslant \gamma(G) \leqslant n_{1}$. Thus, in both the cases $\gamma(G) \geqslant 3$. Hence, $n_{1}=2$. Thus, $G \cong K_{2} \square H_{2}$.

Let $n_{2} \geqslant 2$.
Then $\gamma(G) \leqslant \min \left\{2 \gamma\left(H_{2}\right), n_{2} \gamma\left(K_{2}\right)\right\}=\min \left\{2 \gamma\left(H_{2}\right), n_{2}\right\}(1)$.
From (1) we have $\gamma(G)=2$ only when $H_{2}$ has a universal vertex, since $n_{2} \geqslant 2$.

Next, we consider the case when $\gamma\left(H_{2}\right) \geqslant 2$.
Let $n_{2} \geqslant 5$.
Suppose that $H_{2}$ contains a vertex $v_{i}$ of degree $\left(n_{2}-2\right)$ and $v_{i}$ is not adjacent to $v_{j}$, then $\gamma\left(H_{2}\right)=2$. Now, a minimum dominating set of $G$ is $D=\left\{u_{1} v_{i}, u_{2} v_{i}, u_{1} v_{j}\right\}$ and $\gamma(G)=3$. Suppose that $H_{2}$ contains a vertex of degree at most $\left(n_{2}-3\right)$, then $\gamma\left(H_{2}\right)=2$. Let $v_{p}$ be a vertex of degree $\left(n_{2}-3\right)$ and is not adjacent to $v_{q}$ and $v_{r}$ in $H_{2}$. Then, in $G$ the vertices $u_{1} v_{i}$ and $u_{2} v_{i}$ dominate $2 n_{2}-4$ vertices and the remaining four vertices $u_{1} v_{q}, u_{1} v_{r}, u_{2} v_{q}$ and $u_{2} v_{r}$ cannot be dominated by a single vertex. Hence, in these cases $\gamma(G) \geqslant 3$. Thus, $n_{2} \leqslant 4$.

Chapter 5. Domination criticality in the Cartesian product of 142 graphs

Now, by an exhaustive verification of all graphs with $n_{2} \leqslant 4$ it follows that $G \cong K_{2} \square C_{4}$.

## Illustration of Theorem 5.1.1

Fig 5.1: (i) $G=K_{2} \square C_{4}, \gamma(G)=2$ (ii) $G=K_{2} \square K_{1,4}, \gamma(G)=2$.

Corollary 5.1.2. Let $G \cong H_{1} \square H_{2}$ be a connected graph. Then $G$ is $2-\gamma$-vertex critical if and only if $G=C_{4}$.

Proof. In Theorem 5.1.1 we have characterized the Cartesian product of graphs with $\gamma(G)=2$. Hence, we need to prove the theorem only for such $G$ s.

First, note that $G \cong K_{2} \square C_{4}$ is not $2-\gamma$ - vertex critical.

Now, consider $G \cong K_{2} \square K_{n_{2}}$, where $n_{2} \geqslant 3$. Then, a minimum dominating set $D=\left\{u_{1} v_{x}, u_{2} v_{x}\right\}$ of $G$ contains a vertex from each layer of $K_{n_{2}}$. Now, let a vertex $u_{i} v_{p}$ where $p \in$ $\left\{1,2, \ldots, n_{2}\right\}$, be deleted. If $p=x$, then we can find another
minimum dominating set $D=\left\{u_{1} v_{y}, u_{2} v_{y}\right\}$. If $p \neq x$, then the minimum dominating set $D=\left\{u_{1} v_{x}, u_{2} v_{x}\right\}$ of $G$ remains the same. Thus, in both the cases $\gamma(G-v)=\gamma(G)=2 \forall v \in V(G)$. Hence, $H_{2}=K_{2}$

Consider $G \cong K_{2} \square H_{2}$ where $H_{2}$ is a not complete graph with a universal vertex $v_{p}$. Then, a minimum dominating set $D=\left\{u_{1} v_{p}, u_{2} v_{p}\right\}$ of $G$ contains a vertex from each layer of $H_{2}$. Now, let a vertex $u_{1} v_{q}$ where $q \in\left\{1,2, \ldots, n_{2}\right\}$, be deleted. If $p \neq q$, then the minimum dominating set $D=\left\{u_{1} v_{x}, u_{2} v_{x}\right\}$ of $G$ remains the same. If $p=q$, then in $G$ the vertex $u_{2} v_{q}$ dominate the $n_{2}$ vertices $u_{2} v_{i}$ and the remaining $n_{2}$ vertices cannot be dominated by a single vertex, since we have deleted the universal vertex from the layer of $H_{2}$. Hence, $\gamma(G) \geqslant 3$. Thus, $G \cong$ $K_{2} \square H_{2}$ is not $2-\gamma$ - vertex critical.

Corollary 5.1.3. Let $G \cong H_{1} \square H_{2}$ be a connected graph. Then $G$ is $2-\gamma$ - edge critical if and only if $G=C_{4}$.

Proof. In Theorem 5.1.1 we have characterized the Cartesian product of graphs with $\gamma(G)=2$. Hence, we need to prove the theorem only for such $G \mathrm{~s}$.

Chapter 5. Domination criticality in the Cartesian product of

First, note that $G \cong K_{2} \square C_{4}$ is not $2-\gamma$ - edge critical.

Consider $G \cong K_{2} \square H_{2}$, where $H_{2}$ is a not complete graph with a universal vertex or a complete graph with $n_{2} \geqslant 3$. Let an edge $u_{1} v_{p}-u_{2} v_{i}$ where $i \in\left\{1,2,3, \ldots, n_{2}\right\}$, be added. Then, the addition of an edge does not make either $G$ a complete graph or a graph with a universal vertex. Thus, $\gamma(G)$ remains the same. Hence, $H_{2}=K_{2}$.

Corollary 5.1.4. Let $G \cong H_{1} \square H_{2}$ be a connected graph. Then $\gamma_{c}(G)=\gamma(G)=2$ if and only if $H_{1}=K_{2}$ and $H_{2}$ has a universal vertex.

Proof. It suffices to show that the dominating set of $G$ in Theorem 5.1.1 is connected.

Consider $G \cong K_{2} \square C_{4}$. Then a minimum dominating set of $G$ is $D=\left\{u_{1} v_{1}, u_{2} v_{3}\right\}$ and $\gamma(G)=2$. From Fig 5.1, it is clear that, $\langle D\rangle$ is disconnected.

Consider $G \cong K_{2} \square H_{2}$ where $H_{2}$ is a complete graph or a not complete graph with a universal vertex $v_{p}$.

Then a minimum dominating set of $G$ is $D=\left\{u_{1} v_{p}, u_{2} v_{p}\right\}$ and $<D>$ is connected. Hence, $\gamma_{c}(G)=\gamma(G)=2$.

Corollary 5.1.5. Let $G \cong H_{1} \square H_{2}$ be a connected graph. Then $G$ is $2-\gamma_{c}$ - vertex critical if and only if $G=C_{4}$.

Corollary 5.1.6. Let $G \cong H_{1} \square H_{2}$ be a connected graph. Then $G$ is $2-\gamma_{c}$ - edge critical if and only if $G=C_{4}$.

Theorem 5.1.7. Let $G \cong H_{1} \square H_{2}$ be a connected graph. Then $\gamma(G)=3$ if and only if $G$ is the Cartesian product of any one of the following graphs where,
(a) $H_{1}=K_{3}$ or $P_{3}$ and $H_{2}$ has a universal vertex.
(b) $H_{1}=K_{2}$ and $H_{2}$ has a vertex of degree $n_{2}-2$.
(c) $H_{1}=K_{2}$ and $H_{2}$ has a vertex $v_{r}$ of degree $n_{2}-3$ and is not adjacent to the vertices $v_{p}$ and $v_{q}$ with $N\left[v_{p}\right] \cup N\left[v_{q}\right] \cup\left\{v_{r}\right\}=V\left(H_{2}\right)$.
(d) $H_{1}=K_{3}$ or $P_{3}$ and $H_{2}=C_{4}$.

Proof. Let $G \cong H_{1} \square H_{2}$ where $H_{1}$ is a $K_{3}$ or $P_{3}$ and $H_{2}$ has a universal vertex $v_{i}$. Then, a minimum dominating set of $G$ is $D=\left\{u_{1} v_{i}, u_{2} v_{i}, u_{3} v_{i}\right\}$ and $\gamma(G)=3$.

If $G \cong K_{2} \square H_{2}$ where $H_{2}$ has a vertex $v_{j}$ of degree $n_{2}-2$ and $v_{j}$ is not adjacent to $v_{p}$ in $H_{2}$, then a minimum dominating set of $G$ is $D=\left\{u_{1} v_{j}, u_{2} v_{j}, u_{1} v_{p}\right\}$ and $\gamma(G)=3$.

Further if $G \cong K_{2} \square H_{2}$ where $H_{2}$ has a vertex $v_{r}$ of degree

Chapter 5. Domination criticality in the Cartesian product of 146 graphs
$n_{2}-3$ and is not adjacent to the vertices $v_{p}$ and $v_{q}$ with $N\left[v_{p}\right] \cup$ $N\left[v_{q}\right] \cup\left\{v_{r}\right\}=V\left(H_{2}\right)$, then a minimum dominating set of $G$ is $D=\left\{u_{1} v_{r}, u_{2} v_{p}, u_{2} v_{q}\right\}$ and $\gamma(G)=3$.

Now, $G \cong H_{1} \square C_{4}$ where $H_{1}$ is a $K_{3}$ or $P_{3}$, then a minimum dominating set of $G$ is $D=\left\{u_{1} v_{1}, u_{2} v_{3}, u_{3} v_{1}\right\}$ and $\gamma(G)=3$.

Conversely suppose that $\gamma(G)=3$.
(I) Suppose that both $H_{1}$ and $H_{2}$ are complete graphs, where $n_{1}, n_{2} \geqslant 4$.

Then $\gamma(G) \geqslant \min \{4,4\}=4$. Thus, at least one graph (say) $H_{1}$ has order $n_{1} \leqslant 3$. But $\gamma(G)=3$ only when $H_{1}$ is a $K_{3}$. Hence, $G \cong K_{3} \square K_{n_{2}}$ where $n_{2} \geqslant 3$.
(II) Suppose that $H_{1}$ is a complete graph and $H_{2}$ is not a complete graph.

If $n_{1}, n_{2} \geqslant 4$, then $\gamma(G) \geqslant 4$. Thus, to prove the theorem we have to consider the following cases.
(1) Let $n_{1}=2$ and $n_{2}=3$, then $\gamma(G)=2$.
(2) Let $n_{1}=2$ and $n_{2} \geqslant 4$.

Consider $G \cong K_{2} \square H_{2}$. From (1) we have $\gamma(G) \leqslant \min \left\{2 \gamma\left(H_{2}\right), n_{2}\right\}$. Thus it is clear that we do not have to consider the case when $\gamma\left(H_{2}\right)=1$, since $\gamma(G)=3$. Hence, $\gamma\left(H_{2}\right) \geqslant 2$.

If $\gamma\left(H_{2}\right) \geqslant 3$, then $\gamma(G) \geqslant 4$. Hence, we need consider only the case when $\gamma\left(H_{2}\right)=2$.

Now, suppose that $H_{2}$ is not a complete graph with $\gamma\left(H_{2}\right)=2$.

Suppose that a minimum dominating set of $H_{2}$ is $D=\left\{v_{p}, v_{q}\right\}$.

Let a minimum dominating set of $G$ be $D=\left\{u_{1} v_{p}, u_{1} v_{q}, u_{2} v_{p}\right\}$. The vertices $u_{1} v_{p}$ and $u_{1} v_{q}$ dominate $n_{2}+2$ vertices in $G$. Now, the remaining $2 n_{2}-\left(n_{2}+2\right)=n_{2}-2$ vertices will be dominated by a single vertex $u_{2} v_{p}$, only if $\operatorname{deg}\left(v_{p}\right)=n_{2}-2$. Hence, $H_{2}$ has a vertex of degree $n_{2}-2$. This, proves (b).

Let a minimum dominating set of $G$ contain a vertex $u_{1} v_{r}$ where $v_{r}$ is not a neighbour of $v_{p}$ and $v_{q}$ in $H_{2}$. The vertex $u_{1} v_{r}$ dominate the $n_{2}-1$ vertices $u_{1} v_{x}$ and $u_{2} v_{r}$, where $x \neq r \in$ $\left\{1,2, \ldots, n_{2}\right\}$ in $G$. If the dominating set contain the vertex $u_{2} v_{r}$, then the vertices $u_{1} v_{r}$ and $u_{2} v_{r}$ dominate $2 n_{2}-4$ vertices in $G$. The remaining four vertices $u_{1} v_{q}, u_{1} v_{q}, u_{2} v_{p}$ and $u_{2} v_{q}$ cannot be dominated by a single vertex and hence $\gamma(G) \geqslant 3$. Thus,

Chapter 5. Domination criticality in the Cartesian product of 148 graphs
the dominating set does not contain the vertex $u_{2} v_{r}$. Since, a minimum dominating set of $G$ contain the vertex $u_{1} v_{r}$ and $v_{r}$ is not a neighbour of $v_{p}$ and $v_{q}$ in $H_{2}$, the dominating set of $G$ should contain the vertices $u_{2} v_{p}$ and $u_{2} v_{q}$. Now, the remaining $2 n_{2}-\left(n_{2}-1\right)=n_{2}+1$ vertices will be dominated by the vertices $u_{2} v_{p}$ and $u_{2} v_{q}$, only if $N\left[v_{p}\right] \cup N\left[v_{q}\right]=V\left(H_{2}\right)-v_{r}$. Hence, $H_{2}$ has a vertex $v_{r}$ of degree $n_{2}-3$ and is not adjacent to the vertices $v_{p}$ and $v_{q}$ with $N\left[v_{p}\right] \cup N\left[v_{q}\right] \cup\left\{v_{r}\right\}=V\left(H_{2}\right)$. This, proves (c).
(3) By an exhaustive verification of all graphs with $n_{2}=4$ it follows that $G \cong K_{3} \square C_{4}$.
(4) Let $n_{1}=3$ and $n_{2} \geqslant 4$.

Consider $G \cong K_{3} \square H_{2}$. Let $\gamma\left(H_{2}\right) \geqslant 2$, then $\gamma(G) \geqslant 4$. Thus, $H_{2}$ has a universal vertex.
(5) Let $n_{2}=3$ and $n_{1} \geqslant 3$.

Consider $G \cong K_{n_{1}} \square P_{3}$, then a minimum dominating set of $G$ is
$D=\left\{u_{1} v_{1}, u_{1} v_{2}, u_{1} v_{3}\right\}$. The vertex $u_{1} v_{1}$ dominate the vertices $u_{i} v_{1}$ where $i \in\left\{1,2, \ldots, n_{1}\right\}$, since $H_{1}$ is a complete graph. Similarly, the vertices $u_{1} v_{2}$ and $u_{1} v_{3}$ dominate the remaining
vertices in $G$. Thus, $\gamma(G)=3$.
(III) Suppose that both $H_{1}$ and $H_{2}$ are not complete graphs. If $n_{1}, n_{2} \geqslant 4$, then $\gamma(G) \geqslant 4$. Hence, $n_{1}=3$ and $n_{2} \geqslant 4$.

If $\gamma\left(H_{2}\right) \geqslant 3$, clearly $\gamma(G) \geqslant 4$. Hence, the domination number of $H_{2}$ is at most 2 .

We know that $\gamma(G) \leqslant \min \left\{3 \gamma\left(H_{2}\right), n_{2}\right\}$.
If $\gamma\left(H_{2}\right)=1$ where $v_{i}$ is a universal vertex in $H_{2}$, then $\gamma(G)=3$. Hence, $G \cong P_{3} \square H_{2}$ where $H_{2}$ has a universal vertex.

Now, suppose that $\gamma\left(H_{2}\right)=2$ and $n_{2} \geqslant 6$, then by a similar argument of $\mathrm{II}(2)$ it follows that $\gamma(G) \geqslant 4$. Hence, $n_{2} \leqslant 5$.

By an exhaustive verification of all graphs with $n_{2}=3,4,5$ it follows that $G \cong P_{3} \square C_{4}$.

## Illustration of Theorem 5.1.7.

Fig 5.2: (a) $G=P_{3} \square K_{1,3}, \gamma(G)=3$.
(b) $G=K_{2} \square C_{4}, \gamma(G)=3$.
(c) $G=K_{2} \square K_{3,3}, \gamma(G)=3$.
(d) $G=P_{3} \square C_{4}, \gamma(G)=3$.

Chapter 5. Domination criticality in the Cartesian product of 150 graphs

Corollary 5.1.8. Let $G \cong H_{1} \square H_{2}$ be a connected graph. Then $G$ is a $3-\gamma$-vertex critical graph if and only if $H_{1}=H_{2}=K_{3}$.

Proof. It suffices to prove that $\gamma(G-v)<\gamma(G) \forall v \in G$ of Theorem 5.1.7.

Consider $G \cong K_{3} \square K_{n_{2}}$ where $n_{2} \geqslant 4$. Then, a minimum dominating set $D=\left\{u_{1} v_{x}, u_{2} v_{x}, u_{3} v_{x}\right\}$ of $G$ contains a vertex from each layer of $K_{n_{2}}$. Now, let a vertex $u_{i} v_{p}$ where $p \in$ $\left\{1,2, \ldots, n_{2}\right\}$, be deleted. If $p=x$, then we can find another minimum dominating set $D=\left\{u_{1} v_{y}, u_{2} v_{y}, u_{3} v_{y}\right\}$. If $p \neq x$, then the minimum dominating set $D=\left\{u_{1} v_{x}, u_{2} v_{x}, u_{3} v_{x}\right\}$ of $G$ remains the same. Thus, in both cases $\gamma(G-v)=\gamma(G)=3$ $\forall v \in V(G)$. Hence, $H_{2}=K_{3}$.

Consider $G \cong K_{3} \square H_{2}$ or $G \cong P_{3} \square H_{2}$ where $H_{2}$ has a universal vertex $v_{i}$. Then, a minimum dominating set $D=\left\{u_{1} v_{i}, u_{2} v_{i}, u_{3} v_{i}\right\}$ of $G$ contains a vertex from each layer of $H_{2}$. Now, let a vertex $u_{1} v_{q}$ where $q \in\left\{1,2, \ldots, n_{2}\right\}$, be deleted. If $i \neq q$ then, the minimum dominating set $D=\left\{u_{1} v_{i}, u_{2} v_{i}, u_{3} v_{i}\right\}$ of $G$ remains the same. If $p=i$, then in $G$, the vertices $u_{2} v_{i}$ and $u_{3} v_{i}$ dominate the $2 n_{2}$ vertices and the remaining $n_{2}$ vertices
$u_{1} v_{x}$, where $q \in\left\{1,2, \ldots, n_{2}\right\}$ cannot be dominated by a single vertex, since we have deleted the universal vertex from the layer of $H_{2}$. Hence, $\gamma(G) \geqslant 3$. Thus $\gamma(G-v) \geqslant \gamma(G) \forall v \in V(G)$. Hence, $G \cong K_{3} \square H_{2}$ or $G \cong P_{3} \square H_{2}$ is not 3 - $\gamma$ - vertex critical.

Consider $G \cong K_{2} \square H_{2}$ where $H_{2}$ has a vertex $v_{i}$ of degree $\left(n_{2}-2\right)$ and is not adjacent to the vertex $v_{j}$. Then, a minimum dominating set of $G$ is $D=\left\{u_{1} v_{i}, u_{2} v_{i}, u_{1} v_{j}\right\}$ and $\gamma(G)=3$. Now, let a vertex $u_{1} v_{q}$ where $q \in\left\{1,2, \ldots, n_{2}\right\}$, be deleted. If $i \neq$ $q$, then the minimum dominating set $D=\left\{u_{1} v_{i}, u_{2} v_{i}, u_{1} v_{j}\right\}$ of $G$ remains the same. If $q=i$, then in $G$, the vertices $u_{2} v_{i}$ and $u_{1} v_{j}$ dominate the $n_{2}+1$ vertices and the remaining $n_{2}-1$ vertices $u_{1} v_{x}$ cannot be dominated by a single vertex, since we have deleted the vertex $u_{1} v_{i}$ from the layer of $H_{2}$. Hence, $\gamma(G) \geqslant 3$ and $G \cong K_{2} \square H_{2}$, where $H_{2}$ has a vertex $v_{i}$ of degree $\left(n_{2}-2\right)$, is not $3-\gamma$ - vertex critical.

Consider $G \cong K_{2} \square H_{2}$, where $H_{2}$ has a vertex $v_{p}$ of degree at most $\left(n_{2}-3\right)$ and $v_{p}$ is not adjacent to $v_{q}$ and $v_{r}$. Then then by a similar argument, as in the above case, it follows that $\gamma(G) \geqslant 3$. Hence, $G \cong K_{2} \square H_{2}$, where $H_{2}$ has a vertex of degree at most $\left(n_{2}-3\right)$, is not $3-\gamma$ - vertex critical.

Chapter 5. Domination criticality in the Cartesian product of 152 graphs

Consider $G \cong K_{3} \square C_{4}, G \cong P_{3} \square C_{4}$ and $G \cong K_{2} \square C_{5}$. In all these cases $G$ is not $3-\gamma$ - vertex critical.

Corollary 5.1.9. Let $G \cong H_{1} \square H_{2}$ be a connected graph. Then $G$ is a 3- $\gamma$ - edge critical graph if and only if $H_{1}=H_{2}=K_{3}$.

Proof. It suffices to prove that $\gamma(G+e)=2 \forall e \notin G$ of Theorem 5.1.7.

Consider $G \cong K_{3} \square H_{2}$ or $G \cong P_{3} \square H_{2}$, where $H_{2}$ has a universal vertex $v_{1}$ and $n_{2} \geqslant 4$. Then, a minimum dominating set of $G$ is $D=\left\{u_{1} v_{1}, u_{2} v_{1}, u_{3} v_{1}\right\}$. In $G$, the vertex $u_{1} v_{1}$ dominate the $n_{2}$ vertices $u_{1} v_{i}$, where $i \in\left\{1,2,3, \ldots, n_{2}\right\}$ and $u_{2} v_{1}$ dominate the $n_{2}$ vertices $u_{2} v_{i}$, where $i \in\left\{1,2,3, \ldots, n_{2}\right\}$. Let an edge $u_{1} v_{1}-u_{2} v_{p}$, be added. Then, in $G$ the vertex $u_{1} v_{1}$ dominate the $n_{2}+1$ vertices $u_{1} v_{i}, u_{2} v_{p}$, where $i \in\left\{1,2,3, \ldots, n_{2}\right\}$ and $u_{2} v_{1}$ dominate the $n_{2}-1$ vertices $u_{2} v_{i}$, where $i \neq p \in$ $\left\{1,2,3, \ldots, n_{2}\right\}$ and $u_{3} v_{1}$ dominate the $n_{2}$ vertices $u_{3} v_{i}$, where $i \in\left\{1,2,3, \ldots, n_{2}\right\}$. Hence, the minimum dominating set $D=$ $\left\{u_{1} v_{1}, u_{2} v_{1}, u_{3} v_{1}\right\}$ of $G$ remains the same. Thus, $n_{2}=3$. By an exhaustive verification of all such graphs, it follows $G$ is a $3-\gamma$ - edge critical graph if and only if $H_{1}=H_{2}=K_{3}$.

Consider $G \cong K_{2} \square H_{2}$, where $H_{2}$ has a vertex $v_{i}$ of degree $n_{2}-2$ and $v_{i}$ is not adjacent to $v_{j}$. Then, a minimum dominating set of $G$ is $D=\left\{u_{1} v_{i}, u_{2} v_{i}, u_{1} v_{j}\right\}$. In $G$, the vertex $u_{1} v_{i}$ dominate the $n_{2}-1$ vertices $u_{1} v_{p}$, where $p \neq j \in\left\{1,2,3, \ldots, n_{2}\right\}$ and $u_{2} v_{i}$ dominate the $n_{2}-1$ vertices $u_{2} v_{p}$, where $p \neq j \in$ $\left\{1,2,3, \ldots, n_{2}\right\}$. Let an edge $u_{1} v_{i}-u_{2} v_{j}$, be added. Then, in $G$ the vertex $u_{1} v_{i}$ dominate the $n_{2}$ vertices $u_{1} v_{p}, u_{2} v_{j}$, where $p \neq j \in\left\{1,2,3, \ldots, n_{2}\right\}$ and $u_{2} v_{1}$ dominate the $n_{2}-1$ vertices $u_{2} v_{p}$, where $p \neq j \in\left\{1,2,3, \ldots, n_{2}\right\}$ and the remaining one vertex $u_{1} v_{j}$ is not dominated by the vertices $u_{1} v_{i}$ and $u_{2} v_{i}$. Hence, the minimum dominating set $D=\left\{u_{1} v_{i}, u_{2} v_{i}, u_{1} v_{j}\right\}$ of $G$ remains the same. Thus, $G \cong K_{2} \square H_{2}$, where $H_{2}$ has a vertex $v_{i}$ of degree $n_{2}-2$, is not $3-\gamma$ - edge critical.

Consider $G \cong K_{2} \square H_{2}$, where $H_{2}$ has a vertex $v_{p}$ of degree at most $\left(n_{2}-3\right)$ and $v_{p}$ is not adjacent to $v_{q}$ and $v_{r}$. Then, by a similar argument, as in the above case, it follows that $\gamma(G)=3$. Hence, $G \cong K_{2} \square H_{2}$ where $H_{2}$ has a vertex of degree at most $\left(n_{2}-3\right)$, is not $3-\gamma$ - edge critical.

In all other cases, $G$ is not $3-\gamma$ - edge critical.

Corollary 5.1.10. Let $G \cong H_{1} \square H_{2}$ be a connected graph. Then

Chapter 5. Domination criticality in the Cartesian product of
$\gamma_{c}(G)=\gamma(G)=3$ if and only if $H_{1}=K_{3}$ or $P_{3}$ and $H_{2}$ has a universal vertex.

Proof. It suffices to prove that the dominating set of $G$ in Theorem 5.1.7 is connected.

Consider $G \cong K_{3} \square H_{2}$ or $G \cong P_{3} \square H_{2}$, where $H_{2}$ has a universal vertex $v_{i}$.

Then, a minimum dominating set of $G$ is $D=\left\{u_{1} v_{i}, u_{2} v_{i}, u_{3} v_{i}\right\}$ and $\gamma(G)=3$. Also, $<D>$ is connected. Hence, $\gamma_{c}(G)=3$.

Consider $G \cong K_{2} \square H_{2}$, where $H_{2}$ has a vertex $v_{j}$ of degree $\left(n_{2}-2\right)$ and $v_{j}$ is not adjacent to $v_{x}$.

Then, a minimum dominating set of $G$ is $D=\left\{u_{1} v_{j}, u_{2} v_{j}, u_{1} v_{x}\right\}$ and $\gamma(G)=3$. Also, $\left\langle D>\right.$ is disconnected, since $v_{j}$ is not adjacent to $v_{x}$ in $H_{2}$. Hence, $\gamma_{c}(G) \geqslant 4$.

Consider $G \cong K_{2} \square H_{2}$, where $H_{2}$ has a vertex $v_{p}$ of degree $\left(n_{2}-3\right)$ and $v_{p}$ is not adjacent to $v_{q}$ and $v_{r}$ with $N\left[v_{p}\right] \cup N\left[v_{q}\right] \cup$ $\left\{v_{r}\right\}=V\left(H_{2}\right)$.

Then, a minimum dominating set of $G$ is $D=\left\{u_{1} v_{p}, u_{2} v_{q}, u_{2} v_{r}\right\}$ and $\gamma(G)=3$. Also, $\left\langle D>\right.$ is disconnected, since $v_{p}$ is not adjacent to $v_{q}$ and $v_{r}$ in $H_{2}$. Hence, $\gamma_{c}(G) \geqslant 4$.

In all other cases, $\gamma(G)=3$ and $<D>$ is disconnected. Hence, $\gamma_{c}(G) \geqslant 4$.

Corollary 5.1.11. Let $G \cong H_{1} \square H_{2}$ be a connected graph. Then $G$ is a $3-\gamma_{c}$ - vertex critical graph if and only if $H_{1}=H_{2}=$ $K_{3}$.

Corollary 5.1.12. Let $G \cong H_{1} \square H_{2}$ be a connected graph. Then $G$ is a $3-\gamma_{c}$ - edge critical graph if and only if $H_{1}=H_{2}=K_{3}$.

### 5.2 Vertex criticality in grids

Theorem 5.2.1. Let $G \cong P_{n_{1}} \square P_{n_{2}}$. Then $G$ is vertex critical if and only if $G \cong P_{2} \square P_{2}$.

Proof. It suffices to prove the converse.

Let $G \cong P_{n_{1}} \square P_{n_{2}}$, where $n_{1}, n_{2} \geqslant 3$.
Let $u_{i} v_{j} \in D$, where $i \neq 1, n_{1}$. Since, each vertex in $D$ will dominate at most five vertices, it will dominate two vertices from the $P_{n_{2}}$ - layer at $u_{i}$ and two vertices each from the $P_{n_{2}}$ - layer at $u_{i-1}$ and $P_{n_{2}}$ - layer at $u_{i+1}$, where $u_{i-1}, u_{i+1}$ are the neighbours of $u_{i}$ in $P_{n_{1}}$. Let a vertex $u_{i} v_{j-1}$, be deleted.

Chapter 5. Domination criticality in the Cartesian product of 156 graphs

Then, the minimum dominating set $D$ of $G$ remains the same Hence, $G$ is not a vertex critical graph. Thus, $n_{1}=n_{2}=2$.

Theorem 5.2.2. Let $G \cong P_{n_{1}} \square P_{n_{2}}$. If $n_{1}, n_{2} \geqslant 4$, then a minimal dominating set of $G$ is disconnected.

Proof. Let $u_{i} v_{j} \in D$. Since, the maximum degree of a vertex in $G$ is four, each vertex in $D$ will dominate at most five vertices, it will dominate two vertices from the $P_{n_{2}}$ - layer at $u_{i}$ and two vertices each from the $P_{n_{2}}$ - layer at $u_{i-1}$ and $P_{n_{2}}$ - layer at $u_{i+1}$, where $u_{i-1}, u_{i+1}$ are the neighbours of $u_{i}$ in $P_{n_{1}}$.

Now, suppose that the vertex $u_{p} v_{j+1} \in D$. If $p \neq i$, then $<D>$ is disconnected. If $p=i$, then $D$ should contain a vertex either from $u_{i-1} v_{x}-u_{i-1} v_{y}$ or from $u_{i+1} v_{x}-u_{i+1} v_{y}$, since $n_{1}, n_{2} \geqslant 4$. Then, $<D>$ is disconnected.

Corollary 5.2.3. Let $G \cong P_{n_{1}} \square P_{n_{2}}$. Then $\gamma_{c}(G)=\gamma(G)$ if and only if $G$ is any one of the following graphs where,
(a) $G \cong P_{2} \square P_{2}$.
(b) $G \cong P_{2} \square P_{3}$.
(c) $G \cong P_{3} \square P_{3}$.
(d) $G \cong P_{3} \square P_{4}$.

## Concluding Remarks

In this thesis we have discussed mainly two metric related notions - the diameter variability and the diameter vulnerability, in graph products. Also studied are the notions of the component factors and the domination criticality. This study is quite far from being complete. We list below some problem which we found are interesting, but could not be attempted for various reasons.

1. Obtain an upper bound for $D^{k}(G * H)$ and $D^{-k}(G * H)$ where $* \in\{\square, \boxtimes, \circ\}$.
2. Characterize the graphs with $f^{\prime}(G * H)=\operatorname{diam}(G)+1$, where $* \in\{\boxtimes, \circ\}$.
3. Characterize the graphs with $f^{\prime}(G)=f(G)$.
4. Study some other component factors of the graph products
5. Characterize the graphs with $\gamma(G * H)=2,3$ where $* \in\{\boxtimes, \circ\}$.
6. Characterize the graphs with $\gamma_{c}(G * H)=2,3$ where $* \in\{\boxtimes, \circ\}$.

| $\kappa(G)$ | - Vertex connectivity of $G$ |
| :--- | :--- |
| $\kappa^{\prime}(G)$ | - Edge connectivity of $G$ |
| $G \cong H$ | $-G$ is isomorphic to $H$ |
| $G \square H$ | - Cartesian product of $G$ and $H$ |
| $G \boxtimes H$ | - Strong product of $G$ and $H$ |
| $G \circ H$ | - Lexicographic product of $G$ and $H$ |
| $D^{-k}(G), D^{k}(G), D^{0}(G)$ | - Diameter variability of $G$ |
| $Q_{n}$ | - Hypercube on $n$ vertices |
| $K_{n_{1}} \square K_{n_{2}} \square \ldots \square K_{n_{k}}$ | - Hamming graph |
| $f(G)$ | - Fault diameter of $G$ |
| $f^{\prime}(G)$ | - Diameter vulnerability of $G$ |
| $C_{w}(u, v)$ | $-w$-container between $u$ and $v$ |
| $D_{w}(G)$ | $-w$ - wide diameter of $G$ |
| $\gamma(G)$ | - Domination number |
| $\gamma_{c}(G)$ | - Connected domination number |
